CONTENTS

Preface	xi
About the Editor	xiii
About the Contributors	xiv

PART I. THE DISCIPLINE OF CRIMINOLOGY

1. Criminology as Social Science: Paradigmatic Resiliency and Shift in the 21st Century <i>J. Mitchell Miller, University of Texas at San Antonio</i>	2
2. History and Evolution of Criminology <i>Charles F. Wellford, University of Maryland</i>	10
3. Criminology and Public Policy <i>Todd R. Clear, John Jay College of Criminal Justice</i> <i>Natasha A. Frost, Northeastern University</i>	18

PART II. CORRELATES OF CRIME AND VICTIMIZATION

4. Age and Crime <i>Leana A. Bouffard, Washington State University</i>	28
5. Aggression and Crime <i>Kevin M. Beaver, Florida State University</i>	36
6. Citizenship and Crime <i>Ramiro Martinez Jr., Florida International University</i>	44
7. Weather and Crime <i>Derral Cheatwood, University of Texas at San Antonio</i>	51
8. Education and Crime <i>Gordon A. Crews, Marshall University</i>	59
9. Families and Crime <i>Leslie Gordon Simons, University of Georgia</i>	67
10. Gender and Crime <i>Janet T. Davidson, Chaminade University of Honolulu</i> <i>Meda Chesney-Lind, University of Hawaii</i>	76

11. Guns and Crime	85
<i>Gary Kleck, Florida State University</i>	
12. Intelligence and Crime	93
<i>John Paul Wright and Danielle Boisvert, University of Cincinnati</i>	
13. Mental Illness and Crime	100
<i>Scott Blough, Tiffin University</i>	
14. Neighborhood Influences on Crime	110
<i>Chris L. Gibson, University of Florida</i>	
<i>Holly Ventura Miller, University of Texas at San Antonio</i>	
15. Employment and Crime	118
<i>Robert Apel, State University of New York at Albany</i>	
16. Peers and Crime	125
<i>Dana L. Haynie, The Ohio State University</i>	
17. Race/Ethnicity and Crime	133
<i>Matthew Pate, State University of New York at Albany</i>	
<i>William C. Plouffe Jr., Kutztown University</i>	
18. Religion and Crime	144
<i>Kent R. Kerley, University of Alabama at Birmingham</i>	
19. Social Class and Crime	153
<i>Michael T. Costelloe and Raymond J. Michalowski, Northern Arizona University</i>	
20. Victimization	162
<i>Bonnie S. Fisher and Bradford W. Reynolds, University of Cincinnati</i>	
21. Immigration and Crime	173
<i>Hoan N. Bui, University of Tennessee at Knoxville</i>	

PART III. THEORIES OF CRIME AND JUSTICE

22. Biological Theory	184
<i>Angela D. Crews, Marshall University</i>	
23. Classical Perspectives	201
<i>Andy Hochstetler, Iowa State University</i>	
24. Critical Criminology	210
<i>David O. Friedrichs, University of Scranton</i>	
25. Cultural Criminology	219
<i>Jeff Ferrell, Texas Christian University</i>	
26. Cultural Transmission Theory	228
<i>Mark T. Berg, University of Missouri–St. Louis</i>	
<i>Eric A. Stewart, Florida State University</i>	
27. Deterrence and Rational Choice Theories	236
<i>Raymond Paternoster, University of Maryland</i>	
28. Feminist Criminology	245
<i>Susan F. Sharp, University of Oklahoma</i>	
29. Labeling and Symbolic Interaction Theories	253
<i>Sean Maddan, University of Tampa</i>	
<i>Ineke Haen Marshall, Northeastern University</i>	
30. Life Course Criminology	262
<i>Wesley G. Jennings, University of Louisville</i>	
<i>Alex R. Piquero, University of Maryland</i>	
31. Psychological Theories of Crime	271
<i>John W. Clark, Troy University</i>	

32. Routine Activities	279
<i>Marie Skubak Tillyer, University of Texas at San Antonio</i>	
<i>John E. Eck, University of Cincinnati</i>	
33. Self-Control Theory	288
<i>Travis C. Pratt and Jonathon A. Cooper, Arizona State University</i>	
34. Social Construction of Crime	296
<i>Stuart Henry, San Diego State University</i>	
35. Social Control Theory	305
<i>Christopher J. Schreck, Rochester Institute of Technology</i>	
<i>Travis Hirschi, University of Arizona</i>	
36. Social Disorganization Theory	312
<i>Jeffery T. Walker, University of Arkansas, Little Rock</i>	
37. Social Learning Theory	323
<i>Ronald L. Akers, University of Florida</i>	
<i>Wesley G. Jennings, University of Louisville</i>	
38. Strain Theories	332
<i>Robert S. Agnew, Emory University</i>	
39. Theoretical Integration	340
<i>Michael G. Turner and Kristie R. Blevins, University of North Carolina at Charlotte</i>	
40. Criminal Justice Theories	349
<i>Peter Kraska, Eastern Kentucky University</i>	
41. Convict Criminology	356
<i>Stephen C. Richards, University of Wisconsin–Oshkosh</i>	
<i>Greg Newbold, University of Canterbury, New Zealand</i>	
<i>Jeffrey Ian Ross, University of Baltimore</i>	

PART IV. MEASUREMENT AND RESEARCH IN CRIMINOLOGY

42. Drug Abuse Warning Network (DAWN) and Arrestee Drug Abuse Monitoring (ADAM)	366
<i>Denise Herz, California State University, Los Angeles</i>	
<i>Christine Crossland, U.S. Department of Justice</i>	
43. Crime Classification Systems: NCVS, NIBRS, and UCR	375
<i>Lynn Pazzani and George Tita, University of California, Irvine</i>	
44. Crime Reports and Statistics	383
<i>Callie Marie Rennison, University of Missouri–St. Louis</i>	
45. Citation and Content Analysis	391
<i>Ellen G. Cohn, Florida International University</i>	
46. Crime Mapping	398
<i>Marc L. Swatt, Northeastern University</i>	
47. Edge Ethnography	406
<i>Richard Tewksbury, University of Louisville</i>	
48. Experimental Criminology	413
<i>Anthony A. Braga, Harvard University and University of California, Berkeley</i>	
49. Fieldwork: Observation and Interviews	422
<i>Wilson R. Palacios, University of South Florida</i>	
50. Program Evaluation	428
<i>Jodi Lane, University of Florida</i>	
51. Quantitative Criminology	437
<i>Robert Brame, University of North Carolina at Charlotte</i>	

PART V. TYPES OF CRIME

- | | |
|---|-----|
| 52. Campus Crime | 448 |

PREFACE

Criminology has experienced tremendous growth over the last few decades, which is evident, in part, by the widespread popularity and increased enrollment in criminology and criminal justice departments at the undergraduate and graduate levels, both across the United States and internationally. An evolutionary paradigmatic shift has accompanied this criminological surge in definitional, disciplinary, and pragmatic terms. Though long identified as a leading sociological specialty area, criminology has emerged as a stand-alone discipline in its own right, one that continues to grow and is clearly here to stay. Today, criminology remains inherently theoretical but is also far more applied in focus and thus more connected to the academic and practitioner concerns of criminal justice and related professional service fields. Contemporary criminology is also increasingly interdisciplinary and thus features a broad variety of ideological orientations to and perspectives on the causes, effects, and responses to crime.

21st Century Criminology provides straightforward and definitive overviews of nearly 100 key topics comprising traditional criminology and its more modern outgrowths. The individual chapters have been designed to serve as a “first-look” reference source for most criminological inquires. The contributor group is composed of several well-known discipline figures and emerging younger scholars who provide authoritative overviews coupled with insightful discussion that will quickly familiarize researchers, students, and general readers alike with fundamental and detailed information for each topic.

This two-volume set begins by defining the discipline of criminology and observing its historical development to date (“Part I: The Discipline of Criminology”). The various social (e.g., poverty, neighborhood, and peer/family influences), personal (e.g., intelligence, mental illness), and demographic (e.g., age, race, gender, and immigration) realities that cause, confound, and mitigate crime and crime control are featured in “Part II: Correlates of Crime and Victimization.” The chapters in this section consider each correlate’s impact, both independently and in a broader social ecological context. The sociological origins of

theoretical criminology are observed across several chapters that stress classical, environmental, and cultural influences on crime and highlight peer group, social support, and learning processes. Examination of these criminological theory chapters quickly confirms the aforementioned interdisciplinary nature of the field, with chapters presenting biological, psychological, and biosocial explanations and solutions for crime (“Part III: Theories of Crime and Justice”).

Part IV (“Measurement and Research in Criminology”) provides sound introductory overviews of the various quantitative and qualitative designs and techniques employed in criminological research. Comparison of the purposes and application of these research methods across various crime and justice topics illustrates the role of criminologists as social scientists engaged in research enterprises wherein single studies fluctuate in focus along a pure–applied research continuum. This section also addresses the measurement of crimes with attention to major crime reporting and recording systems.

Having established a theoretical–methodological symmetry as the scientific foundation of criminology, and increasingly the field of criminal justice, Part V (“Types of Crime”) considers a wide range of criminal offenses. Each chapter in this section thoroughly defines its focal offense and considers the related theories that frame practices and policies used to address various leading violent, property, and morality crimes. These chapters also present and critically evaluate the varying level of empirical evidence, that is, research confirmation, for competing theoretical explanations and justice system response alternatives that are conventionally identified as best practices.

Ostensibly, an accurate and thorough social science knowledge base—theoretically driven and empirically validated—stands to render social betterment in terms of reduced crime and victimization through the development of research–based practices. This science–practitioner relationship is featured, advocated, and critiqued in the final section, Part VI (“Criminology and the Justice System”). Here, the central components of the American juvenile and criminal justice systems (law enforcement,

courts, and corrections) are presented from a criminology–criminal justice outlook that increasingly purports to leverage theory and research (in particular, program evaluation results) toward realizing criminal justice and related social policy objectives. Beyond the main system, several chapters consider the role and effectiveness of several popular justice system and wrap-around component initiatives (e.g., specialty courts, restorative justice, and victim services).

Acknowledgments

The content of *21st Century Criminology* was designed in collaboration with Advisory Board members (Robert Brame, Nicole Leeper Piquero, Travis C. Pratt, Jeffery T. Walker, and John L. Worrall) who also assisted in securing leading scholars as contributors. The professionalism of the Sage folks kept the project on track. Jim Brace-Thompson and Sanford Robinson facilitated development, Carla Freeman oversaw production, and Laura Notton and

Leticia M. Gutierrez addressed a plethora of issues concerning the online contracting and submission system. Equally vital to the project’s completion, managing editor Alison Routh was in the trenches interacting with the authors and troubleshooting problems that unavoidably arise with an undertaking of this size. A special acknowledgement of appreciation is due to Holly Ventura Miller for unswerving loyalty and moral support.

Connected to both the sociological origins of criminology (i.e., theory and research methods) and the justice systems’ response to crime and related social problems, as well as coverage of major crime types, this two-volume set offers a comprehensive overview of the current state of criminology. From student term papers and master’s theses to researchers commencing literature reviews, *21st Century Criminology* is a ready source by which to quickly access authoritative knowledge on a range of key issues and topics central to contemporary criminology.

J. Mitchell Miller
University of Texas at San Antonio

ABOUT THE EDITOR

J. Mitchell Miller is professor and chair of the Department of Criminal Justice at the University of Texas at San Antonio. He received his PhD in sociology, with a specialization in criminology, from the University of Tennessee in 1996. While he was a doctoral student, he served as graduate research associate for the Society for the Study of Social Problems and participated in the American Sociological Association Honors Program. From 1996 through 2006, he served on the faculty of the former College of Criminal Justice and then the Department of Criminology and Criminal Justice at the University of South Carolina, where he held affiliate appointments with the College of Social Work and the School of Environmental Studies. While at the University of South Carolina, Dr. Miller also served as director of graduate studies in Drugs and Addictions, as lead evaluator of the Moscow Police Command College (a U.S. State Department democratization initiative), and as interim director of the Southern Violence and Substance Abuse Prevention Center.

Dr. Miller's generalist research agenda involves mixed-methodological criminological theory testing and criminal and juvenile justice program evaluation as well as drug ethnography. He has conducted funded research for various

state and federal agencies, including the National Institute of Justice, the Bureau of Justice Assistance, the Office of Juvenile Justice and Delinquency Prevention, and the U.S. Department of Education. His publications have appeared in a range of social science outlets, including *Justice Quarterly*, the *Journal of Research in Crime and Delinquency*, *Crime & Delinquency*, *The American Sociologist*, *Humanity & Society*, the *Journal of Drug Issues*, and the *Journal of Criminal Justice*. His recent books include *Criminology: A Brief Introduction* (2nd ed., 2008), with Chris Schreck and Rick Tewksbury; *Crime & Criminals* (2nd ed., 2009), with Frank Scarpetti and Amie Nielsen; and *Criminology* (2nd ed., 2008), with Leonard Glick.

Dr. Miller is the former editor of the *Journal of Crime and Justice*, the *Journal of Criminal Justice Education*, and *The Encyclopedia of Criminology* (Vols. I–III, 2005). Currently, he is immediate president of the Southern Criminal Justice Association. His active research includes evaluation of a cognitive restructuring initiative for serial inebriates incarcerated in the Texas Department of Criminal Justice East Texas Treatment Facility and development of a bioterrorist prevention plan for the San Antonio River Authority.

ABOUT THE CONTRIBUTORS

Robert S. Agnew is Samuel Candler Dobbs Professor of Sociology and chair of the Sociology Department at Emory University. He has published four books and approximately 70 articles on the causes of crime and delinquency, with his most recent books being *Juvenile Delinquency: Causes and Control* (2009), *Why Do They Do It? A General Theory of Crime and Delinquency* (2005), and *Pressured Into Crime: An Overview of General Strain Theory* (2006). He is best known for his development of general strain theory, one of the leading theories of crime and delinquency. He has served as associate editor of *Theoretical Criminology* and on the editorial boards of *Criminology*, *Social Forces*, and other journals. A Fellow of the American Society of Criminology, he has been active in many professional organizations and groups dealing with crime and delinquency.

Ronald L. Akers, PhD, is a professor of criminology and sociology at the University of Florida. He is former chair of the Department of Sociology and Director of the Center for Studies in Criminology and Law. He is past president of the American Society of Criminology, a Fellow of that society, and recipient of its prestigious Sutherland Award. He is also past president of the Southern Sociological Society and has held various other influential leadership positions in criminology and sociology. Dr. Akers has authored more than 100 journal articles and book chapters. He is the author of *Criminological Theories: Introduction, Evaluation, and Application*; *Law and Control in Society*; *Drugs, Alcohol and Society*; *Deviant Behavior: A Social Learning Approach*; and *Social Learning and Social Structure: A General Theory of Crime and Deviance*, and was coeditor of *Social Learning Theory and the Explanation of Crime: A Guide for the New Century*. His extensive scholarly history has involved developing and testing social learning theory of crime and deviant behavior and analyzing and conducting research on theory and policy in criminology, criminal justice, law, and deviance.

Leanne Fiftal Alarid is an associate professor in the Criminal Justice Department at the University of Texas at San Antonio. She was previously at the University of Missouri—Kansas City after she earned her PhD from

Sam Houston State University. Dr. Alarid has authored/coauthored journal articles in the area of corrections, gender and crime, and policing in journals such as *Justice Quarterly*, the *Journal of Research in Crime and Delinquency*, and the *Journal of Criminal Justice*. She has authored/edited six books, including *Community-Based Corrections* and *Corrections: A Contemporary Introduction*.

Geoffrey P. Alpert is a professor of criminology and criminal justice at the University of South Carolina. For the past 25 years, his research interests have included policing strategies, behaviors, management and decision making. He has been the principal investigator on research funded by the National Institute of Justice on the use of force, emergency driving, and police officer behavior. His recent books include *Managing Accountability Systems for Police Conduct: Internal Affairs and External Oversight* (with J. Noble), and *Understanding Police Use of Force: Officers, Suspects and Reciprocity* (with R. Dunham).

Tammy L. Anderson is an associate professor in the University of Delaware's Department of Sociology and Criminal Justice. She has published many articles and an edited volume (*Neither Villain nor Victim*, 2008) on drug abuse, identity, gender, race, and stigma. Her forthcoming book *Rave Culture: The Alteration and Decline of a Philadelphia Music Scene* (2009), is a comparative ethnographic study about the social, cultural, and economic forces that alter youth-based music scenes. Her work has been sponsored by the National Science Foundation and the National Institute of Justice.

Robert Apel received his PhD from the University of Maryland in 2004 and is currently an assistant professor in the School of Criminal Justice at the University at Albany, State University of New York. His research interests include the relationship between employment and crime, the long-term impact of incarceration during the transition to adulthood, and situational determinants of injury from violent victimization. His research has appeared in *Criminology*, *Crime & Delinquency*, the *Journal of Quantitative Criminology*, and *Social Forces*.

J. C. Barnes is a doctoral student in the College of Criminology & Criminal Justice at Florida State University. He was named Graduate Student Of The Year by the Southern Criminal Justice Association for 2008. His research interests include the etiology of delinquency and policy evaluation. His work has appeared in *Crime and Delinquency*, *Criminal Justice and Behavior*, *Criminal Justice Policy Review*, *American Journal of Criminal Justice*, and the *Journal of Criminal Justice Education*.

Vidisha Barua, PhD, Esq., is an assistant professor of criminal justice at The Pennsylvania State University Altoona. She received her PhD in criminal justice from Sam Houston State University. She also holds a master's degree in criminal law from the State University of New York at Buffalo. Her book-length publications include the *Press and Media Law Manual* (2002) and *Terrorism in India* (2006). She also has served as executive editor of the *Buffalo Criminal Law Review*. Her research areas include police and prison officers' civil liabilities for the use of Tasers and stun guns, ethical issues in criminal justice, forced medication of death row inmates to induce synthetic sanity, the federal judiciary, and terrorism. She is a licensed attorney in New York.

Gordon Bazemore is currently professor and director of the School of Criminology and Criminal Justice, and director of the Community Justice Institute, at Florida Atlantic University. His research has focused on juvenile justice and youth policy, restorative justice, crime victims, corrections, and community policing. Dr. Bazemore is the author of 68 peer-reviewed articles, 34 book chapters, 25 monographs and technical reports, and numerous other publications. He is first author of three books on juvenile justice reform: *Juvenile Justice Reform and Restorative Justice: Building Theory and Policy From Practice* (with Mara Schiff), *Restorative Juvenile Justice: Repairing the Harm of Youth Crime* (with Lode Walgrave), and *Restorative and Community Justice: Cultivating Common Ground for Victims, Communities and Offenders* (with Mara Schiff). He was recipient of Florida Atlantic University's Researcher of the Year Award in both 1995 and 1999.

Kevin M. Beaver earned his PhD from the University of Cincinnati and is an assistant professor in the College of Criminology and Criminal Justice at Florida State University. His current research examines the biosocial and genetic underpinnings to antisocial behavior.

Michael L. Benson is a professor of criminal justice at the University of Cincinnati. Writing mainly in the areas of white-collar and corporate crime, he has published in numerous journals, including *Criminology*, *Justice Quarterly*, the *Journal of Research and Delinquency*, *American Sociological Review*, the *American Journal of Sociology*, and *Social Problems*. He received the Outstanding Scholarship Award of the Society for the

Study of Social Problems Division on Crime and Juvenile Delinquency for his coauthored book *Combating Corporate Crime: Local Prosecutors at Work*. His most recent books include *Corporate Crime Under Attack: The Fight to Criminalize Business Violence* and *White-Collar Crime: An Opportunity Perspective*.

Mark T. Berg is an assistant professor in the School of Public and Environmental Affairs at Indiana University–Purdue University, Indianapolis. His current research focuses on the social sources of violent behavior and research methods.

Kristie R. Blevins is an assistant professor in the Department of Criminal Justice at the University of North Carolina at Charlotte. She received her PhD in criminal justice at the University of Cincinnati in 2004. Her research interests include environmental crime, corrections, the work reactions of criminal justice employees, and crime prevention. Her work can be found in the *Journal of Offender Rehabilitation*, *Criminal Justice Policy Review*, the *American Journal of Criminal Justice*, *Deviant Behavior*, and the *International Journal of Police Science and Management*.

Scott Blough is chair of the Department of Criminal Justice and Security Studies at Tiffin University, where he specializes in policy development, international crime, terrorism, international security, corrections, and information systems and technology. Prior to this appointment, he served as the chief of the Bureau of Adult Detention in the Ohio Department of Rehabilitation and Correction, where he had oversight of more than 250 jails throughout Ohio. Professor Blough wrote the *Minimum Standards for Jails in Ohio*, which comprises the administrative rules governing jail operations in Ohio. He also served as a lieutenant on the Marion (Ohio) Police Department, where he conducted numerous gang, drug, and gambling investigations. He supervised a multi-jurisdictional gambling task force and successfully investigated and prosecuted the two largest embezzlement cases in Marion's history. He has been a featured lecturer for the National Institute of Corrections, the South Carolina Gang Investigators Association, the Ohio Community Corrections Association, the Southwest Ohio Information Technology Association, the National Association of Government Archives and Records Association, the Buckeye State Sheriff's Association, and the National Sheriffs Association, and he has given presentations at the Criminal Justice Facilities Planning and Management Conference and the Ohio Jail Administrator's annual conference. He was also a featured speaker in Romania, where he lectured on developing standards for adult and juvenile incarceration and probation. In addition to the aforementioned presentations, he has authored numerous publications on international justice and corrections issues, and he is a consultant on justice policy, prison and jail design, security, and technology application

in justice. Professor Blough is ABD (All But Dissertation) from the University of Southern Mississippi International Development/Security Program.

Robert M. Bohm is a professor of Criminal Justice and Legal Studies at the University of Central Florida and a Fellow of the Academy of Criminal Justice Sciences. He has taught both undergraduate and graduate courses on capital punishment since 1985. He regularly makes presentations on capital punishment at the annual meetings of scholarly associations and has been invited to speak on the subject at several universities. He also has served as an expert witness in death penalty cases. Professor Bohm has published numerous books, book chapters, and journal articles on capital punishment. His books include *Deathquest III: An Introduction to the Theory and Practice of Capital Punishment in the United States* (3rd ed., 2008), *The Death Penalty Today* (2008), *America's Experiment With Capital Punishment: Reflections on the Past, Present, and Future of the Ultimate Sanction* (with James R. Acker and Charles S. Lanier, 2nd ed., 2003), and *The Death Penalty in America: Current Research* (1991).

Danielle Boisvert is a doctoral candidate in the Division of Criminal Justice at the University of Cincinnati. Her areas of interests include biosocial criminology, life course criminology, behavioral genetics, and early intervention. Much of her research focuses on the effects of genetic and environmental factors on antisocial behaviors. She has published widely in criminology and genetics journals.

Leana A. Bouffard is an assistant professor of criminal justice at Washington State University. She received her PhD in criminology from the University of Maryland. Her primary area of research interest is criminological theory, especially from a life course perspective. Her current work in this area focuses on the role of various life events, including parenthood and military service, on trajectories of offending. Her other research interests include sexual aggression on college campuses, integrating feminist and mainstream theories of violence against women, and intimate partner violence and police behavior. She has published articles in the leading peer-reviewed journals in the field, including *Criminology*, *Justice Quarterly*, *Crime & Delinquency*, *Criminal Justice and Behavior*, and the *Journal of Criminal Justice*.

Anthony A. Braga is a senior research associate in the Program in Criminal Justice Policy and Management, a lecturer in public policy at Harvard University's John F. Kennedy School of Government, and a Senior Research Fellow in the Berkeley Center for Criminal Justice at Boalt Hall School of Law, University of California, Berkeley. He is also a Fellow of the Academy of Experimental Criminology. His research focuses on working with criminal justice agencies to develop crime prevention strategies to deal with urban problems such as gang violence, illegal gun

markets, and violent crime hot spots. He received his MPA from Harvard University and his PhD in criminal justice from Rutgers University.

Robert Brame is a professor in the Department of Criminal Justice at the University of North Carolina at Charlotte. His current research interests include domestic violence policy, the effects of adolescent employment on criminal behavior, and the use of criminal records to predict future criminal offending. He has also worked on research to study the linkage between juvenile delinquency and adult offending and issues related to capital punishment. His recent research has appeared in *Criminology*, *Crime & Delinquency*, *Criminology & Public Policy*, and the *Journal of Quantitative Criminology*.

Kevin Buckler, PhD, is an assistant professor of criminal justice at the University of Texas at Brownsville and Texas Southmost College. His previous publications have focused on media and crime, crime and public policy, public opinion, and race and ethnicity. Dr. Buckler's research has appeared in the *Journal of Criminal Justice*, the *American Journal of Criminal Justice*, the *Journal of Crime and Justice*, the *Journal of Criminal Justice Education*, and the *Journal of Criminal Justice and Popular Culture*. His current research focus is on county-level voting patterns.

Michael E. Buerger is an associate professor of criminal justice at Bowling Green State University in Ohio. A former police officer, he holds a PhD in criminal justice from Rutgers (1993) and was a National Institute of Justice Visiting Fellow. In addition to street work in New Hampshire and Vermont, he has worked with the Minneapolis (Minnesota) Police Department during the Crime Control Institute's RECAP (Repeat Call Address Policing) and Hot Spots of Crime Experiments, and he was Director of Research for the Jersey City (New Jersey) Police Department on a National Institute of Justice locally initiated research grant. In addition to research on racial profiling, he has written on police training, community policing, and the police role in national intelligence, and he is a charter member of the Futures Working Group, a working collaboration between Police Futurists International and the Federal Bureau of Investigation.

Hoan N. Bui is an associate professor in the Department of Sociology, University of Tennessee at Knoxville. She earned a PhD in social sciences with a concentration in criminology and criminal justice at Michigan State University. Her research centers on the relationship between immigration adaptation and crime with a focus on delinquency and domestic violence among immigrants. Her work emphasizes social class, gender, race, and ethnicity as factors that influence the likelihood of domestic violence experienced by immigrant women and delinquency committed by immigrant adolescents.

Ronald G. Burns is an associate professor and Director of the Criminal Justice Program at Texas Christian University. He earned his PhD from Florida State University. He has published several articles on the topic of environmental crime and is a coauthor of *Environmental Crime: A Sourcebook* and *Environmental Law, Crime and Justice: An Introduction*. His primary area of interest with regard to environmental crime concerns the availability of data to research environmental crime, issues pertaining to environmental justice, and enforcement practices with regard to harms against the environment.

George W. Burruss is an assistant professor in the Center for the Study of Crime, Delinquency and Corrections at Southern Illinois University Carbondale. He received his PhD in criminology and criminal justice from the University of Missouri—St. Louis. He conducts research on criminal justice organizations, including juvenile courts and the police. He has published articles in *Justice Quarterly*, *Policing*, the *Journal of Criminal Justice*, and the *Journal of Criminal Justice Education*.

Dean John Champion (1940–2009) was a professor of criminal justice and sociology, Texas A&M International University, Laredo, until his unexpected passing in February 2009. Dr. Champion formerly taught at the University of Tennessee; California State University, Long Beach; and Minot State University. He earned his PhD from Purdue University and BS and MA degrees from Brigham Young University. Over his 40-year career, Dr. Champion authored more than 40 texts and edited works as well as numerous articles. He held memberships in 11 professional organizations and is a lifetime member of the American Society of Criminology and the Academy of Criminal Justice Sciences. A former Editor of the Academy of Criminal Justice Sciences/Anderson Publishing Series on *Issues in Crime and Justice* and the *Journal of Crime and Justice*, he was a Visiting Scholar at the National Center for Juvenile Justice and a former president of the Midwestern Criminal Justice Association. Dr. Champion's specialty interests included juvenile justice, criminal justice administration, corrections, and statistics/methods.

Derral Cheatwood obtained his PhD from The Ohio State University and is currently a professor of sociology at the University of Texas at San Antonio. His primary areas of research in criminology are capital punishment, media and crime, and homicide. He has served as president of the Homicide Research Working Group and was awarded a Fulbright Scholarship to study European crime data at the Max Planck Institute for Foreign and International Criminal Law in Germany. His articles on the relationship of weather to crime have appeared in *Criminology* and the *Journal of Quantitative Criminology*.

Meda Chesney-Lind, PhD, is a professor of women's studies at the University of Hawaii at Manoa. Nationally

recognized for her work on women and crime, her books include *Girls, Delinquency and Juvenile Justice*; *The Female Offender: Girls, Women and Crime*; *Female Gangs in America*; *Invisible Punishment*; and *Girls, Women and Crime*. She has just finished a book on trends in girls' violence, entitled *Beyond Bad Girls: Gender, Violence and Hype*. She received the Bruce Smith Sr. Award "for outstanding contributions to criminal justice" from the Academy of Criminal Justice Sciences in April 2001. She was named a Fellow of the American Society of Criminology in 1996 and has received the Herbert Block Award for service to the society and the profession from the American Society of Criminology. She has also received the Donald Cressey Award from the National Council on Crime and Delinquency for "outstanding contributions to the field of criminology," the Founders award of the Western Society of Criminology for "significant improvement of the quality of justice," and the University of Hawaii Board of Regents Medal for Excellence in Research. Finally, Chesney-Lind has been included among the scholars working with the Office of Juvenile Justice and Delinquency Prevention's Girls Study Group. In Hawaii, she has worked with the Family Court, First Circuit, advising them on the recently formed Girls Court as well as helping improve the situation of girls in detention.

John W. Clark received his bachelor's degree from the University of Alabama at Birmingham in 1996 and his master's degree in criminal justice in 1998 from University of Alabama. Upon graduation, he designed his own doctoral curriculum, which focused on the interaction between psychology and the criminal justice system. His minor area of concentration was political science. In 2002, Dr. Clark earned his Interdisciplinary PhD from the University of Alabama. He has taught at the University of Alabama and the University of North Alabama and is currently an associate professor at Troy University. His publications include articles in *Law and Psychology Review*, *Behavioral Sciences and the Law*, *Criminal Justice and Behavioral Science*, the *Journal of Criminal Justice*, *Criminal Law Bulletin*, the *Journal of the Legal Profession*, and *Criminal Law Brief*.

Todd R. Clear is a Distinguished Professor at the John Jay College of Criminal Justice of the City University of New York. Dr. Clear earned his PhD in criminal justice from the University at Albany, State University of New York. An expert in the areas of corrections and community justice, Dr. Clear served as founding editor of the American Society of Criminology's policy journal, *Criminology & Public Policy*.

Ellen G. Cohn is currently an associate professor in the Department of Criminology at Florida International University, in Miami. She received her PhD from Cambridge University in 1992. With David Farrington, she has published numerous articles using citation analysis in

criminology and criminal justice. The new techniques they have developed to allow them to use citation analysis to examine the influence of scholars, works, and journals are considered groundbreaking and their book (with Richard Wright), *Evaluating Criminology and Criminal Justice*, is considered one of the leading works in the field of citation analysis. In addition, Dr. Cohn is involved in research into the relationship among weather, temporal variables, and criminal behavior. She has published extensively in this area and is a well-known expert in the field.

Jonathon A. Cooper received his MA degree in criminal justice from Boise State University and is currently a doctoral student in the School of Criminology and Criminal Justice at Arizona State University. His research interests include the areas of theoretical criminology and crime prevention.

Heith Copes is an associate professor in the Department of Justice Sciences at the University of Alabama at Birmingham. He received his PhD in sociology from the University of Tennessee. His research addresses crime from the offender's perspective. He received a grant from the National Institute of Justice to interview federally convicted identity thieves.

Michael T. Costelloe received his PhD from Florida State University in 2004. He is currently an assistant professor in the Department of Criminology and Criminal Justice at Northern Arizona University. His research interests focus on public perceptions of crime and punishment, power, crime and justice, undocumented immigration, research methods, and criminological theory.

Anna Crayton is a third-year doctoral student in the criminal justice program at the John Jay College of Criminal of Criminal Justice/City University of New York Graduate Center. She joined the Prisoner Reentry Institute at the John Jay College of Criminal Justice as a research assistant in March 2006 and in June 2008 became the deputy director of research. Since joining the Prisoner Reentry Institute, she has worked on a number of projects, including the development of a national resource guide to help individuals plan for their education upon release from prison and a quantitative analysis of the effects of long-term incarceration on reentry.

Angela D. Crews is an associate professor of criminal justice at Marshall University in Huntington, West Virginia. She is active in the Academy of Criminal Justice Sciences as the Chair of the Corrections Section, in the American Society of Criminology, and in the Southern Criminal Justice Association. She earned a BS in psychology from Tusculum College (Tennessee), an MA in criminal justice and criminology from East Tennessee State University, and a PhD in criminology from Indiana University of Pennsylvania. Her research interests are varied and involve all aspects of the criminal justice system but share a policy analysis or program evaluation

focus. Most recently, she has been interested in correctional policy analysis and program evaluation, in policies related to the release of ex-prisoners into society, and in comparative policing and corrections. Her areas of teaching include research methods and statistics, corrections, comparative justice systems, and criminological theory. She has authored or coauthored several journal articles, book chapters, encyclopedia entries, and grant proposals, and currently she is developing an edited book on international convict criminology and working on two juvenile crime and violence books with her husband, Dr. Gordon A. Crews.

Gordon A. Crews is an associate professor in the Department of Criminal Justice at Marshall University. Since 1990, he has served as a faculty member and/or academic administrator at Washburn University (Kansas), Cameron University (Oklahoma), Roger Williams University (Rhode Island), Jacksonville State University (Alabama), Valdosta State University (Georgia), and the University of South Carolina at Beaufort. Prior to teaching, Dr. Crews worked in law enforcement as a bloodhound officer and trainer, field training officer, and criminal investigator; in corrections as a training and accreditation manager; and in insurance fraud as an investigator. His publications include books, chapters, and journal articles dealing with school violence, occult/Satanic involvement and youth, and various law enforcement and correctional issues. Since 2000, he has conducted extensive field research in these areas across the United States, United Kingdom, Middle East, Netherlands, Central Europe, Scandinavia, and most recently in Turkey and Ghana.

Christine Crossland is a senior social science analyst with the National Institute of Justice, U.S. Department of Justice. Ms. Crossland is responsible for planning, implementing, testing, evaluating, managing, and reporting on criminal justice grants, contracts, and studies at the institute. She has served as the deputy director of the former U.S. Department of Justice's Arrestee Drug Abuse Monitoring program, where she directed and managed over 40 drug-testing research sites across the country. She is currently working with other government agencies, nonprofit organizations, public and private businesses, and criminal justice and public health agencies to coordinate the establishment of a broad and enhanced research agenda in the area of violence and victimization, drugs and crime, and American Indian and Alaska Native crime and justice issues.

Janet T. Davidson, PhD, is an assistant professor of criminology and criminal justice at Chaminade University of Honolulu. She previously worked as a senior research analyst and project researcher for the Hawaii Department of the Attorney General. Her research interests include predictors of recidivism for community correctional populations, risk and need assessment instruments, and gender and crime. She has been active in applied research

in Hawaii for both the state correctional agencies and the Federal District of Hawaii Probation Office, in particular in the area of recidivism. She has also been active in the evaluation of the recently formed Girls Court in Hawaii.

Mathieu Deflem obtained his PhD in sociology from the University of Colorado in 1996. He previously held professional positions at Kenyon College and Purdue University and at present is an associate professor at the University of South Carolina. His main areas of expertise include the sociology of law, social control and policing, terrorism and counterterrorism, and sociological theory. His recent empirical research has focused on the sociology and criminology of terrorism and the law enforcement dimensions of counterterrorism in the United States and in various international settings.

Matt DeLisi is coordinator of criminal justice studies, associate professor of sociology, and faculty affiliate with the Center for the Study of Violence at Iowa State University. He has published nearly 100 scholarly books, articles, and chapters, mostly on career criminals, psychopathy, self-control theory, inmate behavior, homicide offenders, and molecular/behavioral genetics and crime.

Roger G. Dunham is a professor of sociology at the University of Miami, Florida. His research focuses on policing strategies and decision making; specifically, he has conducted research on use of force, emergency driving, racial profiling, and attitudes toward the police. His recent books include *Understanding Police Use of Force: Officers, Suspects and Reciprocity* (2004); *Critical Issues in Policing* (4th ed., 2005); *Policing: Continuity and Change* (2006), and *Crime and Justice in America* (2nd ed., 2002).

John E. Eck is a professor of criminal justice at the University of Cincinnati, where he studies crime pattern formation and prevention. With Lin Liu, he coedited *Artificial Crime Analysis Systems: Using Computer Simulations and Geographic Information System*, the first book on the simulation of crime patterns. With Ronald V. Clarke, he is the coauthor of *Crime Analysis for Problem Solvers*, a manual for police officials on how to prevent crime. Eck received a master's degree in public policy from the University of Michigan in 1977 and his doctorate from the University of Maryland in 1994. From 1977 to 1994, he directed research at the Police Executive Research Forum in Washington, DC. Eck has written extensively on problem-oriented policing, crime mapping, drug markets, computer simulation of crime patterns, and crime prevention. He was a member of the National Academy of Sciences Committee on Police Policy and Research and is a judge for the British Home Office's Tilley Award for Problem-Solving Excellence. He is the author of numerous articles on policing, crime mapping and analysis, evaluation methods, and crime simulation.

Terry D. Edwards is an associate professor in the Department of Justice Administration at the University of Louisville, Kentucky. He received his MPA at Golden Gate University and his juris doctor degree at the University of Louisville's School of Law. His research interests include police civil liability, environmental crime, and constitutional law. Professor Edwards has authored, or coauthored several publications, including a textbook on criminal law, various book chapters on criminal and environmental law, and a number of articles on police legal issues.

Roger Enriquez is an associate professor of criminal justice at the University of Texas at San Antonio and serves as the Graduate Director for the master's degree program in justice policy. He holds a juris doctor degree from the University of Iowa College of Law. Mr. Enriquez has a robust research agenda that includes policing, crime, courts, gangs, Latinos in the criminal justice system, and empirical testing of anecdotal legal theories with respect to jurors and secondary effects. He has published numerous articles in law reviews and peer-reviewed publications. Recent law review articles have appeared in the *Journal of Gender, Race & Justice*, the *University of Texas Hispanic Journal of Law & Policy*, the *Washington College of Law Criminal Law Brief*, the *Criminal Law Bulletin*, and the *American University Journal of Gender, Social Policy & the Law*. His recent peer-reviewed publications have appeared in the *Journal of Criminal Justice*, the *Journal of Criminal Justice Education*, *Western Criminology Review*, and the *Journal of Ethnicity in Criminal Justice*.

David P. Farrington, OBE, is a professor of psychological criminology at the Institute of Criminology, Cambridge University, and an adjunct professor of psychiatry at Western Psychiatric Institute and Clinic, University of Pittsburgh. He is a Fellow of the British Academy of Criminology, the Academy of Medical Sciences, of the British Psychological Society, and of the American Society of Criminology. He is also an Honorary Life Member of the British Society of Criminology and of the Division of Forensic Psychology of the British Psychological Society. He is a chartered forensic psychologist, co-chair of the U.S. National Institute of Justice Study Group on Transitions from Juvenile Delinquency to Adult Crime, a member of the board of directors of the International Observatory on Violence in Schools, a member of the board of directors of the International Society of Criminology, joint editor of the journal *Criminal Behaviour and Mental Health*, and a member of the editorial boards of 15 other journals. He has been president of the American Society of Criminology (the first person from outside North America to be elected to this office), president of the European Association of Psychology and Law, president of the British Society of Criminology, president of the Academy of Experimental Criminology, chair of the Division of Forensic Psychology

of the British Psychological Society, vice chair of the U.S. National Academy of Sciences Panel on Violence, and co-chair of the U.S. Office of Juvenile Justice and Delinquency Prevention Study Groups on Serious and Violent Juvenile Offenders and on Very Young Offenders. He has received BA, MA, and PhD degrees in psychology from Cambridge University; an honorary ScD from Trinity College, University of Dublin; the Sellin-Glueck Award of the American Society of Criminology for international contributions to criminology; the Sutherland Award of the American Society of Criminology for outstanding contributions to criminology; and numerous other international awards. His major research interest is in developmental criminology, and he is director of the Cambridge Study in Delinquent Development and coinvestigator of the Pittsburgh Youth Study. In addition to more than 470 published articles and chapters on criminological and psychological topics, he has published 70 books, monographs, and government publications, one of which (*Understanding and Controlling Crime*, 1986) won the prize for distinguished scholarship of the American Sociological Association Criminology Section.

Jeff Ferrell earned his PhD in sociology from the University of Texas at Austin and is currently a professor of sociology at Texas Christian University and visiting professor of criminology at the University of Kent, UK. He is the author of the books *Crimes of Style; Tearing Down the Streets; Empire of Scrounge*; and, with Keith Hayward and Jock Young, *Cultural Criminology: An Invitation*. He is also the coeditor of four books that explore the theories, subject matter, and methods of cultural criminology: *Cultural Criminology*, *Cultural Criminology Unleashed*, *Ethnography at the Edge*, and *Making Trouble*. Dr. Ferrell is the founding and current editor of the New York University Press book series *Alternative Criminology* and one of the founding and current editors of the journal *Crime, Media, Culture*.

Bonnie S. Fisher is a professor in the Division of Criminal Justice at the University of Cincinnati. Her recent work includes examining the predictors of repeat sexual victimization and drug-facilitated sexual assault among college women and the criminal justice implications of the detection of genital–anal injury in forensic sexual assault exams. She has edited *Campus Crime: Legal, Social and Political Perspectives* (2nd ed.) and *Violence at Work: Causes, Patterns, and Prevention*. Professor Fisher has authored more than 100 articles, chapters, and reports addressing college student victimization, sexual victimization, stalking of and violence toward female college students, gendered fear, violence against older women, and workplace violence.

David O. Friedrichs is a professor of sociology/criminal justice and Distinguished University Fellow at the University of Scranton. He is the author of *Trusted Criminals: White Collar Crime in Contemporary Society* (1996, 2004, 2007) and *Law in Our Lives: An Introduction*

(2001, 2006) and editor of *State Crime, Volumes I and II* (1998). He has published well over 100 journal articles, book chapters, encyclopedia entries, and essays and well over 300 book reviews. He has been a visiting professor or guest lecturer at many colleges and universities, including the University of South Africa and Flinders University in Australia. He has served as editor of *Legal Studies Forum* (1985–1989) and as president of the White Collar Crime Research Consortium (2002–2004). In November 2005, he received a Lifetime Achievement Award from the Division on Critical Criminology of the American Society of Criminology.

Natasha A. Frost is an assistant professor in the College of Criminal Justice at Northeastern University. Dr. Frost earned her PhD in criminal justice from the City University of New York's Graduate School and University Center. Dr. Frost's research and teaching interests are in the area of punishment and social control. She has served as founding managing and associate editor of *Criminology & Public Policy*.

Chris L. Gibson is an assistant professor in the Department of Sociology and Criminology and Law at the University of Florida, a W. E. B. Du Bois Fellow of the National Institute of Justice, and a research affiliate of the Jim Walter Partnership at the University of South Florida. He received his PhD in criminology and criminal justice at the University of Nebraska in 2005. His current research focuses on neighborhood contextual effects on child and adolescent development and outcomes, neighborhoods and quality of life, applied quantitative methods, and biosocial/life-course criminology. As a W. E. B. Du Bois Fellow, Dr. Gibson is conducting research on how neighborhood conditions in Chicago influence Hispanic children's involvement in antisocial behaviors.

Angela R. Gover, PhD, is an associate professor at the School of Public Affairs at the University of Colorado at Denver. She received her PhD in criminology and criminal justice at the University of Maryland. Her research interests include policy-relevant family violence issues, violence against women, gender and crime, and evaluation research. For the past 6 years, Dr. Gover has been working on two Department of Justice–funded research projects involving law enforcement and judicial responses to domestic violence. Her current project is examining the impact of proactive enforcement of no-contact orders on victim safety and repeat victimization in cases of domestic violence.

Patricia M. Harris is a professor of criminal justice and associate dean of the College of Public Policy at the University of Texas at San Antonio. She received her PhD in criminal justice from Rutgers—The State University of New Jersey. Her research interests include offender classification, community supervision of offenders, and the regulation of crime risks. She has also published in the area of crime prevention.

Richard D. Hartley is an assistant professor in the Department of Criminal Justice at the University of Texas at San Antonio. His research interests include disparities in sentencing practices, prosecutorial and judicial discretion, race/ethnicity and crime, and quantitative methods. His research has appeared in the *Journal of Criminal Justice*, *Justice Quarterly*, and the *Journal of Contemporary Criminal Justice*.

Dana L. Haynie is an associate professor of sociology at The Ohio State University. She received a PhD in sociology from The Pennsylvania State University in 1999. Her current research focuses on the social relationships that facilitate delinquent behavior and the developmental implications of exposure to violence.

Stuart Henry, PhD, is a professor of criminal justice and director of the School of Public Affairs at San Diego State University. Previously, he has been director of the Interdisciplinary Studies Program and associate dean of the College of Lifelong Learning at Wayne State University in Detroit (1999–2006), professor of criminology at Eastern Michigan University (1987–1998), and chair of the Department of Sociology at Valparaiso University (1998–1999). Dr. Henry's research has been funded by the British Economic and Social Science Research Council, the U.S. Federal Management Agency, and the National Science Foundation. He has authored or edited 23 books and more than 100 professional journal articles on the topics of criminological theory, deviant behavior, law and society, and occupational crime. His books include *The Hidden Economy* (1978), *Criminological Theory* (1995, 2006) *Constitutive Criminology* (1996), *What is Crime?* (2001), and *Essential Criminology* (1998, 2004). He serves on the editorial board of *Critical Criminology* and *Theoretical Criminology* and is a member of the Board of the Association for Integrative Studies.

Denise Herz, PhD, is a professor at the California State University, Los Angeles, in the School of Criminal Justice and Criminalistics. Previous to this appointment she was on the faculty of the University of Nebraska at Omaha in the Department of Criminal Justice. Dr. Herz was the site director for the Arrestee Drug Abuse Monitoring Program in Omaha (1996–2001) and in Los Angeles (2003–2004). As part of the Arrestee Drug Abuse Monitoring Program, she authored the National Institute Research in the report "Drugs in the Heartland: Methamphetamine Use in Rural Nebraska." Her current area of research is in juvenile justice, with particular emphasis on mental health and substance abuse issues among offenders, improving the processing of juvenile offenders, and most recently, crossover youth. Denise Herz received her MA and PhD in criminology from the University of Maryland at College Park.

George E. Higgins is an associate professor in the Department of Justice Administration at the University of Louisville. He received his PhD in criminology from

Indiana University of Pennsylvania in 2001. His most recent publications have appeared in *Criminal Justice Studies*, *Deviant Behavior*, *Criminal Justice and Behavior*, *Youth & Society*, and the *American Journal of Criminal Justice*.

Travis Hirschi is professor emeritus in the Department of Sociology at the University of Arizona. Professor Hirschi has authored several books, including *Delinquency Research* (with Hanan Selvin) and *A General Theory of Crime* (with Michael Gottfredson). He earned his PhD in sociology from the University of California, Berkeley.

Andy Hochstetler earned his PhD from the University of Tennessee and is an associate professor of sociology at Iowa State University. Using quantitative and qualitative methodologies, he generally writes on criminal decision making and how offender identity and contexts shape it.

Lorine A. Hughes is an assistant professor in the Department of Criminal Justice at the University of Nebraska at Omaha. She received her PhD in sociology from Washington State University. With James F. Short Jr., she edited the book *Studying Youth Gangs*.

Wesley G. Jennings, PhD, is an assistant professor in the Department of Justice Administration at the University of Louisville and holds a PhD in criminology from the University of Florida. His research interests cover a number of criminological, psychological, and criminal-justice-related areas, but his primary focus is applying semiparametric group-based modeling techniques to examine similarities/differences among groups that demonstrate distinct behavioral trajectories over time. In addition, some of his recent work has focused on testing the cross-cultural applicability of social learning theory among Hispanic populations.

Brian D. Johnson is an assistant professor of criminology and criminal justice at the University of Maryland. He received his PhD in crime, law, and justice from The Pennsylvania State University. His dissertation research was supported by the Forrest Crawford Fellowship for Ethical Inquiry and received the Penn State Alumni Association Dissertation Award. Dr. Johnson has received paper awards for his scholarship from both the American Society of Criminology and the American Sociological Association, and he is a faculty associate of the Maryland Population Research Center. His research examines juvenile transfer to adult court, contextual variations in sentencing, and social inequities in criminal punishments, as well as the use of advanced statistical modeling techniques to study criminal processes. Dr. Johnson recently served as the University of Maryland delegate to the Atlantic Coast Conference Inter-Institutional Academic Collaborative to Study Social Issues in Emerging Democracies in Central and Eastern Europe, and in 2008 he was awarded the Ruth Shonle Cavan Young Scholar Award from the American Society of Criminology.

Catherine Elizabeth Kaukinen is an associate professor in the School of Public Affairs at the University of Colorado at Colorado Springs and is the Director of Academic Programs in Criminal Justice. Dr. Kaukinen received her PhD in sociology in 2001 from the University of Toronto. Her research interests include intimate partner violence, risk and protective factors for violent victimization, and the relationship between family structure and adolescent development. She is currently conducting a National Institute of Justice–sponsored project examining the effect of intensive enforcement of no-contact orders in cases of misdemeanor criminal domestic violence on victim well-being and offender recidivism. Her research has appeared in *Criminology*, the *Journal of Marriage and Family*, the *Journal of Research in Crime and Delinquency*, the *Journal of Interpersonal Violence*, *Violence and Victims*, and *Health and Social Care in the Community*, among other outlets.

Philip R. Kavanaugh is a doctoral candidate in the University of Delaware's Department of Sociology and Criminal Justice. His dissertation research examines the relationship between individual disposition and social context in criminal offending and victimization among individuals with active night lives. In addition to crime and deviance, he maintains interests in theory, culture, and identity.

Kent R. Kerley received the PhD in sociology and criminology from the University of Tennessee. He is an assistant professor and director of the Criminal Justice Honors Program in the Department of Justice Sciences at the University of Alabama at Birmingham. His primary research interests include religiosity and corrections. His work has appeared in the *Journal for the Scientific Study of Religion*, *Justice Quarterly*, *Social Forces*, and *Social Problems*.

David N. Khey, MS, MA, is a doctoral candidate in the Department of Sociology and Criminology and Law at the University of Florida. His recent research efforts have concentrated in examining drug and alcohol arrests in college towns and exploring the recreational use of the plant *Salvia divinorum* among youths. More broadly, his research has investigated the changing nature of forensic technology and testimony in U.S. courts and improving forensic education and training through the use of distance education.

Bitna Kim is an assistant professor in the Department of Criminology at Indiana University of Pennsylvania. She received her PhD from the College of Criminal Justice at Sam Houston State University, as well as a master's degree in psychology from Chungbuk National University in South Korea. Her specific areas of teaching and research interest include statistics, gender issues in criminal justice system, intimate partner homicide, and hate crimes. Her recent publications have

appeared in the *International Journal of Offender Therapy and Comparative Criminology* and *The Southwest Journal of Criminal Justice*.

Gary Kleck is a professor of criminology and criminal justice at Florida State University. He earned his doctorate at the University of Illinois at Urbana–Champaign in 1979. His research has focused on the impact of firearms and gun control on violence, deterrence, crime control, and violence. He has studied gun ownership patterns, the effectiveness of armed self-protection, the frequency of defensive gun use, the impact of offender weapon possession and use on the outcomes of crimes, the effect of gun ownership levels on crime rates, the extent and character of gun trafficking, patterns of support for gun control, and the impact of gun control laws on violence rates. He is the author of *Point Blank: Guns and Violence in America*, which won the 1993 Michael J. Hindelang Award of the American Society of Criminology. More recently, he is the author of *Targeting Guns* (1997) and, with Don B. Kates Jr., *The Great American Gun Debate* (1997) and *Armed* (2001). His articles have appeared in the *American Sociological Review*, the *American Journal of Sociology*, *Social Forces*, *Social Problems*, *Criminology*, the *Journal of Criminal Law and Criminology*, *Law & Society Review*, the *Journal of the American Medical Association*, and other journals. He teaches doctoral students how to do survey research and statistical analysis and how to distinguish good research from bad.

Peter Kraska is a professor and Research Fellow at Eastern Kentucky University. He has published numerous books and journal articles, including a major new textbook, *Criminal Justice and Criminology Research Methods*. His most recent research interests include steroid trafficking, further development of the idea of criminal justice theory, and the militarization of the criminal justice system.

Steven P. Lab is professor of criminal justice and chair of the Department of Human Services at Bowling Green State University. He received his PhD in criminology from Florida State University and has been a visiting professor at Keele University and the Jill Dando Institute of Crime Science at the University College London. He is the author or coauthor of seven books, including *Juvenile Justice: An Introduction* (with John Whitehead) and *Crime Prevention: Approaches, Practices and Evaluation, and Victimology* (with William Doerner), as well as numerous journal articles. He is also a past president of the Academy of Criminal Justice Sciences.

Jodi Lane is an associate professor of criminology, law, and society at the University of Florida. She earned her PhD in social ecology at the University of California, Irvine. Her recent research has focused on fear of crime and program evaluations of juvenile justice programs in California and Florida.

Sean Maddan is an assistant professor in the Department of Criminology at the University of Tampa. His research areas include criminological theory, statistics, research methods, and the efficacy of sex offender registration and notification laws. Articles by Dr. Maddan have appeared in *Justice Quarterly*, *Crime and Delinquency*, and the *Journal of Criminal Justice*. Most recently, Dr. Maddan has authored the book *The Labeling of Sex Offenders* and has coauthored the textbook, *Statistics in Criminology and Criminal Justice*.

David H. Marble is a professor of criminal justice at Collin College in Plano, Texas. He also serves as chair of the Department of Political Science and Criminal Justice. His interests are law, courts, and corrections. He received his MPA in criminal justice administration from the University of Utah in 1995 and is pursuing a PhD in criminology at the University of Texas at Dallas.

Ineke Haen Marshall earned her PhD at Bowling Green State University and is a professor at Northeastern University. She specializes in the study of comparative criminology, ethnicity and crime, self-report methodology, juvenile delinquency, and criminal careers. Her current research focuses on cross-national surveys of juvenile delinquency and comparative examination of homicide. She serves on the editorial board of several international and national journals. She has published widely in leading scholarly periodicals, and she coauthored (with Josine Junger-Tas and Denis Ribeaud) *Delinquency in an International Perspective: The International Self-Report Delinquency Study* (2003). Her other book publications include *Minorities and Crime: Diversity and Similarity Across Europe and the United States* (1997, Sage Publications) and *Between Prohibition and Legalization: the Dutch Experiment in Drug Policy* (with Ed Leuw, 1994, 1996).

Ramiro Martínez Jr. is professor of criminal justice at Florida International University. He received the American Society of Criminology's Division on People of Color and Crime Coramae Richey Mann Award, the Florida International University Faculty Award for Excellence in Research, and the American Sociological Association Latino Section Award for Distinguished Contributions to Research. He has authored *Latino Homicide: Immigration, Violence and Community* (2002), and edited *Immigration and Crime: Race, Ethnicity, and Violence* (2006).

Sheila Royo Maxwell is an associate professor at the School of Criminal Justice at Michigan State University. Her research and publications include the areas of sanctioning, in particular behavioral responses to sanctioning; the efficacy of sanctioning mechanisms across gender, ethnic, and cultural milieus; and cross-cultural patterns of violence, delinquency, and victimization. Dr. Maxwell has received research grants from the National Science Foundation, the National Institute of

Justice, the Bureau of Cultural and Educational Affairs of the U.S. Department of State, and other local and state agencies.

John D. McCluskey earned his PhD from the University at Albany, State University of New York, and is an associate professor in the Department of Criminal Justice at the University of Texas at San Antonio. His research involves understanding police and citizen behavior in the context of everyday encounters, the causes of violence, and the evaluation of the effectiveness of violence intervention efforts.

Raymond J. Michalowski is Regents Professor of Criminology and Criminal Justice at Northern Arizona University. He received a PhD in sociology from The Ohio State University and has written extensively on social class and crime in the books *Order, Law and Crime* (1985); *State-Corporate Crime* (2005); *Crime, Power and Identity* (2006); and articles on the political economy of crime and justice in *Criminology*, *Justice Quarterly*, *Social Justice*, and the *Journal of Research in Crime and Delinquency*.

Holly A. Miller is the assistant dean of undergraduate programs and an associate professor in the College of Criminal Justice at Sam Houston State University. She received her BA from Bethel University in St. Paul, Minnesota, and her PhD in clinical psychology from Florida State University. She teaches, consults, and conducts research in the areas of malingered psychopathology, assessment and treatment of violent offenders, psychopathy, and human diversity issues within the criminal justice system.

Holly Ventura Miller is an assistant professor in the Department of Criminal Justice at the University of Texas at San Antonio and the current National Institute of Justice W. E. B. Du Bois Fellow. She received her PhD in sociology at the University of South Carolina in 2006. Her research interests include criminological theory testing, ethnicity and crime, and program evaluation. Along with Dr. Chris Gibson, she is conducting research on how neighborhood conditions in Chicago influence Hispanic children's involvement in antisocial behaviors.

Jerry Miller, PhD, an industrial-organizational psychologist, is project director of Prodigy, a youth arts-based intervention program, and director of research at the Jim Walter Partnership Center, both at the University of South Florida. With a specialty in evaluation and organizational management, Dr. Miller has been leading the effort to enhance the program fidelity of the Prodigy arts program by directing the systematic manualization of the program as well as the development of methods to assess and monitoring the implementation of the program. In addition, he is leading the effort in developing a program evaluation model that examines the program's practices as part of an effort to identify the core components related to program success. Most of his

academic career has been involved in designing and managing community-based interventions and programs, including economic and job placement, anti-crime activities, and community asset building. He is the recipient of numerous grants in the areas of international training of managers of youth programming, community development, and of projects to serve youth.

Elizabeth Ehrhardt Mustaine, PhD, an associate professor in the Department of Sociology at the University of Central Florida, received her PhD in sociology from The Ohio State University in 1994. Dr. Mustaine has written numerous journal articles on registered sex offenders and sex offender registries, criminal victimization, routine activities theory, violence, violence against women, and stalking. She recently completed work on the National Institute of Justice-funded project “Violence Against Homeless Women.” She has also coauthored a book on issues in criminal justice research. She developed the Domestic Violence Graduate Track in the Department of Sociology at the University of Central Florida, and she teaches the “Child Abuse in Society” course to master’s and PhD students.

Raymund Espinosa Narag is a doctoral student in the School of Criminal Justice at Michigan State University. His research interests focus on communities and crime, criminal victimization, and corrections policy. He is currently one of the recipients of a Fulbright Scholarship to the Philippines.

Greg Newbold is a senior academic at the University of Canterbury in Christchurch, New Zealand, where he has been teaching for the past 20 years. While serving a 7½-year sentence for selling drugs in the 1970s, he wrote an MA thesis on the maximum security prison where he was located. Upon his release in 1980, he commenced work on his PhD, which he completed in 1986. Since then he has written seven books and more than 50 academic articles and is currently recognized as one of New Zealand’s leading criminological authorities. He speaks regularly at overseas conferences and is often consulted by New Zealand government agencies on matters of criminal justice and law enforcement.

Wilson R. Palacios is an associate professor in the Department of Criminology at the University of South Florida. He received his PhD in sociology from the University of Miami. His primary research areas of interest are in the social epidemiology of illicit drug use/abuse, illicit drug markets (social networks), and qualitative research methods and analysis.

Karen F. Parker is a professor in the Department of Sociology and Criminal Justice at the University of Delaware. Her current research interests include exploring the influence of theoretical constructs associated with labor markets and structural disadvantage on urban violence, examining the contextual and spatial dynamics of policing and crime in urban communities, and

incorporating change models into the study of disaggregated homicide rates at the city level. She is the author of *Unequal Crime Decline: Theorizing Race, Urban Inequality and Criminal Violence*.

Matthew Pate is a doctoral candidate in the School of Criminal Justice at the University at Albany, State University of New York. He holds advanced degrees in criminal justice, sociology, and environmental design. His primary research interests are comparative criminal justice, corporal punishment, and policing. Pate is the incoming associate editor for the *Journal of Criminal Justice and Popular Culture*.

Raymond Paternoster is a professor in the Department of Criminology and Criminal Justice at the University of Maryland and a research associate at the Maryland Population Research Center. His current research interests include the theory of and modeling offender decision making, the transition from adolescence to adulthood, and issues pertaining to capital punishment.

Brian K. Payne, PhD, is professor and chair of the Department of Criminal Justice at Georgia State University. His research focuses on elder abuse, family violence, and electronic monitoring. He received his PhD in criminology from Indiana University of Pennsylvania in 1993.

Lynn Pazzani is a doctoral candidate at the University of California, Irvine, in the Department of Criminology, Law and Society. Her research focuses on sexual assault, but she often consults on research design and statistics issues for other topics within criminology. She is currently working on her dissertation on how rape is culturally defined and how responsibility is attributed in sexual assault cases.

Matthew Perdoni is a faculty research associate in the Administration of Justice Program at George Mason University. Mr. Perdoni’s work includes research and publication on the National Institute on Drug Abuse-funded Criminal Justice Drug Abuse Treatment Studies, a landmark research initiative aimed at depicting and evaluating the landscape of substance abuse treatment in the criminal justice system, and the National Drug Court Survey, which examined the treatment practices and the organizational cultures and characteristics of drug courts and their working relationships with community service providers. His current work includes research to estimate the impact of administrator turnover on correctional treatment practices, measuring the annual population of offenders exposed to clinical treatment services, and evaluating the impact of correctional populations on the public health systems. Mr. Perdoni holds a bachelor of arts degree in psychology from Lehigh University, a master of science degree in criminal justice from Virginia Commonwealth University, and is a juris doctor candidate at the David A. Clarke School of Law, at the University of the District of Columbia.

Alex R. Piquero, PhD, is a professor at the University of Maryland Department of Criminal Justice and Criminology, a member of the MacArthur Foundation's Research Network on Adolescent Development, and a member of the National Consortium on Violence Research. He is also executive counselor of the American Society of Criminology, coeditor of the *Journal of Quantitative Criminology*, and a member of the National Academy of Science Panel Assessing the Research Program of the National Institute of Justice. He received a PhD in criminology and criminal justice from the University of Maryland in 1996 and has received several teaching, research, and mentoring awards, including the American Society of Criminology Young Scholar and E-Mail Mentor of the Year Awards and a University of Florida Teacher of the Year Award. His research interests include criminal careers, criminological theory, and quantitative research methods. He has published widely in the fields of criminology, criminal justice, psychology, and sociology, and is coauthor (with Alfred Blumstein and David Farrington) of *Key Issues in Criminal Careers Research*.

William C. Plouffe Jr. is an assistant professor in the Department of Criminal Justice at Kutztown University. Plouffe holds advanced degrees in law and criminal justice as well as undergraduate degrees in philosophy and psychology. His professional background includes over a decade each in legal practice, law enforcement, and military service. Professor Plouffe has authored numerous scholarly articles and books.

Travis C. Pratt received his PhD in criminal justice from the University of Cincinnati and is currently an associate professor in the School of Criminology and Criminal Justice at Arizona State University. He has published more than 50 journal articles and book chapters, primarily in the areas of criminological theory and correctional policy, that have appeared in journals such as *Criminology*, the *Journal of Research in Crime and Delinquency*, *Justice Quarterly*, and *Crime and Justice: A Review of Research*. He is also the author of *Addicted to Incarceration: Corrections Policy and the Politics of Misinformation in the United States* (2009, Sage Publications) and was the recipient of the 2006 Ruth Shonle Cavan Award from the American Society of Criminology.

Amy Reckdenwald is an assistant professor in the School of Criminology and Criminal Justice at Florida Atlantic University. She recently received her doctorate degree in criminology from the University of Florida. Her current research interests include intimate partner homicide, domestic violence, race and gender issues, and capital punishment and sentencing.

Callie Marie Rennison, PhD, is an assistant professor at the University of Missouri—St. Louis, in the Criminology and Criminal Justice Department. She earned her PhD in political science at the University of Houston. Her areas of interest focus primarily on the nature, extent, and

consequences of victimization, with an emphasis on research methodology, quantitative analysis, and measurement. She has a particular interest in examining violence against women and minority groups, such as African Americans and Hispanics. Before joining the faculty at the University of Missouri—St. Louis, she served as a statistician in the Victimization Statistics Unit of the Department of Justice's Bureau of Justice Statistics in Washington, DC. From 2004 to 2006, she was a Post-doctoral Fellow with the National Consortium on Violence Research.

Bradford W. Reynolds has a BA from Weber State University in anthropology and an MS from Weber State University in criminal justice and is a PhD student in criminal justice at the University of Cincinnati. His research interests include crime prevention, victimology and victimization, stalking, and computer-facilitated crimes. Currently, he is working on studies that address the ways in which online social networks act as arenas for cyberstalking of college students, situational crime prevention and cyberstalking, adolescent lifestyles and victimization, and how "broken windows" in schools affect fear of adolescent victimization.

Stephen C. Richards is an associate professor of criminal justice at the University of Wisconsin—Oshkosh. His most recent books include *Behind Bars: Surviving Prison* and *Convict Criminology* (with Jeffrey Ian Ross). Richards is a Soros Senior Justice Fellow and member of the American Society of Criminology National Policy Committee.

Jeffrey Ian Ross, PhD, is an associate professor in the Division of Criminology, Criminal Justice and Social Policy, and a Fellow of the Center for International and Comparative Law, at the University of Baltimore. He has researched, written, and lectured on national security, political violence, political crime, violent crime, corrections, and policing for over two decades. Ross's work has appeared in many academic journals and books, as well as popular outlets. He is the author, coauthor, editor, and coeditor of 13 books, including *Behind Bars: Surviving Prison*, *Convict Criminology*, and *Special Problems in Corrections*. Ross has performed consulting services for Westat; CSR; the U.S. Department of Defense; the Office of Juvenile Justice and Delinquency Prevention, U.S. Department of Justice; the National Institute of Justice, U.S. Department of Justice; the U.S. Department of Homeland Security; and the Intel Science Talent Search. From 1995 through 1998, Ross was a social science analyst with the National Institute of Justice, a Division of the U.S. Department of Justice. In 2003, he was awarded the University of Baltimore's Distinguished Chair in Research Award. Ross worked close to 4 years in a correctional institution.

William Rowe, DSW, is professor and director of the School Social Work at the University of South of Florida.

He holds appointments in the College of Public Health, the AIDS Education and Training Center, and the Moffitt Cancer Center. He was formerly director of the Center for Applied Family Studies and director and professor of the Schools of Social Work at McGill University and Memorial University, and he was originally tenured at the University of Western Ontario. Dr. Rowe has worked extensively in the fields of social work education, child welfare, corrections, health, and HIV. He has provided training and lectures at agencies and universities throughout North America, Europe, the Middle East, South Asia, Australia, and New Zealand.

During his 30 years as a social work educator, he has edited and authored more than 125 scholarly and professional books, articles, monographs, and research papers on a variety of topics. He serves on the editorial board of a number of academic and professional journals, including *Stress, Trauma, and Crisis*; the *Journal of Evidence-Based Social Work*; and *Best Practices in Mental Health*. He has served on numerous national and international boards and committees in both the academic and practice arenas, and he remains an active researcher. He has been at the forefront of evaluating arts intervention programming.

Patti Ross Salinas, JD, PhD, chairs the Criminal Justice Department at the University of Texas at Brownsville and Texas Southmost College. A former city prosecutor for the City of Springfield, Missouri, Dr. Salinas has had diverse research interests and publications. Her current research focus is on delinquency among Hispanic youth.

Claudia San Miguel is an assistant professor of criminal justice within the Department of Behavioral, Applied Sciences, and Criminal Justice at Texas A&M International University in Laredo. She is the coauthor of *The Death Penalty: Constitutional Issues, Commentaries, and Cases* and has published in the area of intelligence-led policing strategies, anti-bully programs, and community crime prevention. She was the coeditor of an issue of the *Journal of Social and Ecological Boundaries* entitled "Immigration: Crime, Victimization, and Media Representation." Dr. San Miguel is working on research involving the trafficking of women and children and has recently traveled to Poland to help form collaborative relationships with their anti-trafficking task force. She has also taught courses for the Department of State in Roswell, New Mexico, on crime types and typologies and global human trafficking at the International Law Enforcement Academy.

Christopher J. Schreck is an associate professor in the Department of Criminal Justice at the Rochester Institute of Technology. His work primarily focuses on using theories of crime to account for the overlap between criminal offending and victimization. Professor Schreck earned his PhD in Crime, Law, and Justice from The Pennsylvania State University.

Jason Scott is an assistant professor in the Department of Criminal Justice at the Rochester Institute of Technology. Dr. Scott received his PhD from the School of Criminal Justice at the University at Albany, State University of New York. While a graduate student at the University at Albany he served as project coordinator for the Police–Community Interaction Project, which sought to define and measure a variety of community-level variables contained in community policing efforts. Dr. Scott's current research interests include comprehensive anti-gang strategies, community policing, and the role of criminal justice agencies in community capacity building.

Susan F. Sharp is a professor of sociology at the University of Oklahoma. In 1996, she obtained a PhD in sociology from the University of Texas at Austin, and she has taught at the University of Oklahoma since that time. Her research interests primarily focus on women and crime, women and the criminal justice system, and the effects of penal policies on the families of offenders. Dr. Sharp is a former chair of the Division on Women and Crime of the American Society of Criminology. She is the founding editor of the division's official journal, *Feminist Criminology*. She is the editor of the textbook *The Incarcerated Woman: Rehabilitative Programming in Women's Prisons*, and she has authored more than 30 journal articles and book chapters, as well as the book *Hidden Victims: The Effects of the Death Penalty on Families of the Accused*.

James F. Short Jr. is professor emeritus of sociology at Washington State University. Since receiving his PhD in sociology from the University of Chicago, he has spent many years investigating and writing about youth street gangs. He is the author or editor of numerous books, including *Group Process and Gang Delinquency* (with Fred L. Strodbeck); *Gang Delinquency and Delinquent Subcultures*; *Delinquency and Society*; *Studying Youth Gangs* (with Lorine A. Hughes); and *Poverty, Ethnicity, and Violent Crime*.

Neal Shover is professor of sociology at the University of Tennessee, Knoxville. His principal areas of interest and expertise are criminal careers, white-collar crime, and ethnographic research methods. A Fellow of the American Society of Criminology, he is author or coauthor of seven books and numerous published articles.

J. Eagle Shutt, JD, MCJ, PhD, is an assistant professor at the University of Louisville's Department of Justice Administration. A former prosecutor, public defender, and judicial clerk, Dr. Shutt's research interests include biosocial criminology, subcultures, and law.

Leslie Gordon Simons is an associate professor in the Department of Child and Family Development at the University of Georgia. She received her doctorate in sociology from Iowa State University, and her research focuses families and delinquency. Specifically, Dr. Simons

is interested in how family structure and family processes, such as quality of parenting, impact adolescent externalizing problems. Her recent work has addressed the ways in which harsh parenting behaviors are related to risky sex, substance use, dating violence, and sexual coercion among adolescents.

John J. Sloan III, PhD, is an associate professor of criminal justice and sociology, senior scientist at the Center for Minority Health, and chair of the Department of Justice Sciences at the University of Alabama at Birmingham. He received his doctorate in sociology from Purdue University. For the past 15 years, he has studied crime and related issues on college and university campuses, including conducting the first ever national-level college student victimization survey in 1994.

Hayden P. Smith is an assistant professor in the University of South Carolina's Department of Criminology and Criminal Justice. His principal focus of study is the intersection of the criminal justice and public health systems. His current works address the dynamic processes of self-injurious behaviors in corrections, jail diversion programs, and re-entry issues facing mentally ill inmates. His other areas of interest include criminological theory and corrections.

Eric A. Stewart is an associate professor in the College of Criminology and Criminal Justice at Florida State University and a member of the Racial Democracy, Crime and Justice Network. His research interests include racial inequality and criminal outcomes, crime over the life course, and multilevel processes on adolescent development.

Christopher J. Sullivan, PhD, is an assistant professor in the University of South Florida's Department of Criminology. He completed his doctorate at Rutgers University in 2005. His research interests include developmental criminology, juvenile delinquency, and research methodology and analytic methods. His recent publications have appeared in *Criminology*, *Youth Violence and Juvenile Justice*, and the *Journal of Research in Crime and Delinquency*. These articles include multiple works on specialization in offending and the effect of shifts in local life circumstances.

Marc L. Swatt is currently an assistant professor at the College of Criminal Justice at Northeastern University. He graduated in 2003 from the University of Nebraska—Omaha. His research interests include criminological theory, quantitative criminology, and spatial crime analysis. His recent publications have been featured in the *Journal of Criminal Justice* and the *Journal of Quantitative Criminology*. He is currently working on a collaborative project that is examining crime trends in a medium-sized Midwestern city.

Faye S. Taxman, PhD, is a professor in the Administration of Justice Program at George Mason University. Dr. Taxman is recognized for her work in the development of the

seamless systems of care models that link the criminal justice with other service delivery systems as well as re-engineering probation and parole supervision services and organizational change models. Her work covers the breadth of the correctional system, from jails and prisons to community corrections and adult and juvenile offenders. She is the senior author of *Tools of the Trade: A Guide to Incorporating Science Into Practice*, a publication of the National Institute on Corrections that is a guidebook for implementation of science-based concepts into practice. She is on the editorial boards of the *Journal of Experimental Criminology* and the *Journal of Offender Rehabilitation*, and she has published articles in the *Journal of Quantitative Criminology*, the *Journal of Research in Crime and Delinquency*, the *Journal of Substance Abuse Treatment*, the *Journal of Drug Issues*, *Alcohol and Drug Dependence*, and *Evaluation and Program Planning*. She received the University of Cincinnati award from the American Probation and Parole Association in 2002 for her contributions to the field. She is a Fellow of the Academy of Experimental Criminology and a member of the Correctional Services Accreditation Panel of England. In 2008, the American Society of Criminology's Division of Sentencing and Corrections recognized her as Distinguished Scholar.

Ian Tebbett is director of the University of Florida Forensic Science Program and a professor in the University of Florida Colleges of Pharmacy and Veterinary Medicine. He holds a bachelor's degree in pharmacy and a PhD degree in forensic toxicology. He has previously held faculty positions in the forensic science programs at the University of Strathclyde, Scotland, and the University of Illinois at Chicago (1988–1992). Dr. Tebbett previously served as director of analytical toxicology and director of the racing laboratory in the University of Florida College of Veterinary Medicine.

Karen J. Terry, PhD, is a professor in criminal justice and executive officer of the doctoral program in criminal justice at John Jay College, City University of New York. She holds a doctorate in criminology from Cambridge University. She has authored several publications on sex offender treatment, management, and supervision, including *Sex Offender Registration and Community Notification: A "Megan's Law" Sourcebook* and *Sexual Offenses and Offenders: Theory, Practice and Policy*. She is also the editor of the periodical *Sex Offender Law Report*, published bimonthly by the Civic Research Institute. She has been involved with numerous research projects regarding sexual offenses and offenders. Most recently, she was the principal investigator for a national study on the nature and scope of child sexual abuse in the Catholic Church from 1950–2002, and she is currently analyzing the causes and context of this crisis.

Richard Tewksbury is a professor of justice administration at the University of Louisville. He holds a PhD in sociology from The Ohio State University. His research

focuses on issues of criminal victimization; sex offenders and responses to sex offenses; and issues of sex, gender, and sexuality. He has published numerous articles drawing on qualitative data, including studies that have used edge ethnographic methods.

Marie Skubak Tillyer is an assistant professor of criminal justice at the University of Texas at San Antonio. She received her doctorate in criminal justice from the University of Cincinnati in 2008, and she received her master's degree in criminal justice from the University of Cincinnati in 2004. Her research has focused on multilevel aspects of guardianship, place management in schools, and the use of environmental criminology to inform the prevention of street violence. Most recently, she has expanded the concept of handlers to explore the prevention possibilities of applying routine activities theory to serious repeat offender problems.

George Tita is an associate professor in the Department of Criminology, Law and Society at the University of California, Irvine. His research is anchored in the community and crime literature, with a special focus on the causes and correlates of interpersonal violence. In addition to exploring how youth gangs impact spatial dimensions of crime, he is also interested in examining how racial and ethnic change at the neighborhood level affects levels and patterns of crime. Dr. Tita has used diverse set of methods in his research, including spatial analysis, quasi-experimental methods (propensity score matching), hedonic models, agent-based models, and social network analysis.

Jeremy Travis became the fourth president of the John Jay College of Criminal Justice on August 16, 2004. Prior to his appointment, President Travis served 4 years as a Senior Fellow affiliated with the Justice Policy Center at the Urban Institute, a nonpartisan research and policy organization in Washington, DC. Travis has taught courses on criminal justice, public policy, history, and law at Yale University, New York University's Wagner Graduate School of Public Service, the New York Law School, George Washington University, and the John Jay College of Criminal Justice. He is the author of *But They All Come Back: Facing the Challenges of Prisoner Reentry* (2005); coeditor (with Christy Visher) of *Prisoner Reentry and Crime in America* (2005); and coeditor (with Michelle Waul) of *Prisoners Once Removed: The Impact of Incarceration and Reentry on Children, Families, and Communities* (2003). He has published numerous book chapters, articles, and monographs on constitutional law, criminal law, and criminal justice policy.

Michael G. Turner is an associate professor and graduate coordinator in the Department of Criminal Justice at the University of North Carolina at Charlotte. His research interests include testing criminological theories and victimization. He has also secured several grants to

address a variety of health-related behaviors that impact the success of college students. He has recently published in the *Journal of Research in Crime and Delinquency*, *Justice Quarterly*, and *Criminal Justice and Behavior*.

Lynne Vieraitis is an associate professor at the University of Texas at Dallas. She earned her PhD in criminology from Florida State University. She received a grant from the National Institute of Justice to interview federally convicted identity thieves.

Gennaro F. Vito is a Distinguished University Scholar and professor in the Department of Justice Administration at the University of Louisville, where he has a faculty appointment in the Administrative Officer's Course of the Southern Police Institute. He holds a PhD in public administration from The Ohio State University. His research interests are concerned with criminal justice policy analysis and program evaluation and police management. His most recent textbook is *Introduction to Criminal Justice Research Methods: An Applied Approach* (2008).

Jeffery T. Walker is a professor of criminal justice and criminology in the Department of Criminal Justice at the University of Arkansas at Little Rock. Dr. Walker also holds joint appointments with the University of Arkansas at Fayetteville and the University of Arkansas Medical School. He earned his PhD from Sam Houston State University in 1992. He has written 6 books and more than 50 journal articles and book chapters, including articles in *Justice Quarterly*, the *Journal of Quantitative Criminology*, and the *Journal of Criminal Justice Education*. He has obtained over \$9 million in grants from the Department of Justice, the National Institute on Drug Abuse, and other agencies. His areas of interest are social/environmental factors of crime and the study of nonlinear dynamics as they relate to crime. He is the immediate past president of the Academy of Criminal Justice Sciences.

Ralph A. Weisheit is Distinguished Professor of Criminal Justice at Illinois State University. He is the author of eight books; his most recent is *Methamphetamine: Its History, Pharmacology, and Treatment*. He is also the author of more than 40 journal articles, as well as numerous book chapters and solicited essays. He has appeared in the *Frontline* documentary film series and the news program *60 Minutes*. His work has also been reported in a variety of magazines and newspapers, including the *Atlantic Monthly*, *U.S. News & World Report*, the *New York Times*, and *USA Today*.

Charles F. Wellford is a professor of criminology and criminal justice at the University of Maryland. He is a Fellow and past president of the American Society of Criminology and a National Life Associate of the National Academy of Sciences. He received his PhD in 1961 from the University of Pennsylvania.

John T. Whitehead is chair of the Department of Criminal Justice and Criminology at East Tennessee State University. He is coauthor, with Steven P. Lab, of *Juvenile Justice* and coauthor, with Mark Jones and Michael Braswell, of *Exploring Corrections in America*. He has published articles on the death penalty, the effectiveness of felony probation, and job burnout in probation and parole.

Scott E. Wolfe is a doctoral student in the School of Criminology and Criminal Justice at Arizona State University. He earned his master's degree in justice administration from the University of Louisville. His publications can be found in *Deviant Behavior*, *Social Science Computer Review*, and the *American Journal of Criminal Justice*. His current research interests are criminological theory testing, computer crime, and child sexual abuse.

Peter B. Wood is a professor of sociology and department head in the Department of Sociology, Anthropology, and Criminology at Eastern Michigan University. Dr. Wood earned his PhD in Sociology at Vanderbilt University and has served on the faculty at the University of Oklahoma and, most recently, Mississippi State University, where he served as department head and director of the Program in Criminal Justice and Corrections. His work examines issues associated with offender decision making, correctional policy and practice, and testing of criminological theories. He recently served as president of Alpha Kappa Delta, the International Sociology Honor Society, and as president of the Southern Criminal Justice Association. He received the Southern Criminal Justice Association's Educator of the Year Award in 2007. Dr. Wood's work has appeared in many peer-reviewed outlets, including *Justice Quarterly*, *Punishment and Society*, *The Prison Journal*, *Crime & Delinquency*, *Criminology*, the *Journal of Criminal Justice*, the *Journal of Research in Crime and Delinquency*, the *Journal of Offender Rehabilitation*, and others.

Robert M. Worley, PhD, is an assistant professor of criminal justice at The Pennsylvania State University Altoona. He received his PhD in criminal justice from Sam Houston State University. His research interests include inappropriate inmate-guard relationships, violent crime, and legal issues in criminal justice. Dr. Worley's publications have appeared in such journals as *Criminal Justice Review*, *Deviant Behavior*, the *American Journal of Criminal Justice*, and *Criminal Law Bulletin*, among others.

John L. Worrall is an associate professor of criminology at the University of Texas at Dallas. His interests are policing, courts, and panel data models. He is coeditor of *The Changing Role of the American Prosecutor* (2008) and editor of the journal *Police Quarterly*. He received his PhD in political science from Washington State University in 1999.

John Paul Wright is an associate professor of criminal justice in the Division of Criminal Justice at the University of Cincinnati. His work focuses on genetic and biological influences on human violent behavior, life course development of serious antisocial behavior, and the interplay between biological processes and environmental stimuli. He has published more than 80 articles and 4 books.

Marvin Zalman is a professor in the Department of Criminal Justice at Wayne State University in Detroit, Michigan. He earned a PhD in criminal justice from the State University of New York at Albany and a JD from Brooklyn Law School. Dr. Zalman's work focuses on constitutional criminal procedure and on criminal justice policies connected with civil liberties, including articles on confessions law and a study of police interrogation attitudes and practices. His most recent work concerns wrongful convictions and includes a jointly authored study of the incidence of wrongful convictions. He is the author of *Criminal Procedure: Constitution and Society*.

PART I

THE DISCIPLINE OF CRIMINOLOGY

CRIMINOLOGY AS SOCIAL SCIENCE

Paradigmatic Resiliency and Shift in the 21st Century

J. MITCHELL MILLER

University of Texas at San Antonio

Criminology is the study of crime, as indicated by the formative Latin terms *crimin* (accusation or guilt) and *-ology* (study of). As an intellectual domain, criminology comprises contributions from multiple academic disciplines, including psychology, biology, anthropology, law, and, especially, sociology. Although the defining statements of criminology are rooted across these diverse areas, contemporary criminology is becoming ever more intertwined with still additional sciences and professional fields such as geography, social work, and public health.

This plurality of influences, often referred to as *multi-disciplinarity*, is altogether logical given the complex subject matter and diverse nature of crime. Scholarly attention to crime from various perspectives allows for an extensive range of research questions to be addressed, making possible a fuller understanding of the criminal mind, the nature of crime, and social control processes. Legal scholarship, for example, ranges from philosophical attention to social justice issues to technocratic factors determinant of case outcome. Alternatively, psychology approaches the topic of crime with a focus on individual-level maladjustment and behavioral abnormality. Sociological criminology differs still by concentrating on the multiple causes and nature of crime, as well as society's reaction to it.

The individuals who study crime, *criminologists*, engage research on virtually every imaginable aspect of illegality and society's reactions to it, ranging from the development of theories of crime causation, the roles and

uses of social control (e.g., police, courts, and corrections), crime prevention, and victimization. Of course, criminologists have also developed substantial knowledge bases on specific offenses, which are often categorized as (a) crimes against property (e.g., burglary, theft, robbery, and shoplifting); (b) crimes against a person (e.g., homicide, assault, and rape); (c) morality/social order crimes (e.g., gambling, prostitution, substance offenses, vandalism); and now (d) technology crime/cybercrime, which overlaps with and often facilitates crime in each of the other categories. The collective basic knowledge that criminologists have generated through the scientific process has great potential for informing social policy and criminal justice practice through enhancement of the effectiveness and efficiency of prevention, intervention, enforcement, and rehabilitative strategies and practices in the 21st century.

This introductory chapter quickly surveys the emergence and evolution of criminology, from seminal contributions to its contemporary state in academe. While tracing criminology's history and acknowledging its intellectual diversity (these matters are more fully addressed in Chapter 2), it is contended that criminology is correctly understood and best practiced as a social science. Furthermore, as a field of scientific inquiry criminology is no longer a specialty area of other established disciplines, such as deviance within sociology or abnormal psychology, but instead is a new and steadily growing independent academic discipline in its own right. Last, the

rise of academic criminal justice is acknowledged as a shaping force on criminology that is steadily moving the discipline toward greater interdisciplinary status and public policy utility (the focus of Chapter 3).

Defining Criminology

The terms *criminology* and *criminologist* are used rather broadly and interchangeably by the news media and in everyday popular culture expression. Criminologists are, in fact, social scientists, but frequently and erroneously they are confused with other crime-related scientific and investigative roles (e.g., forensics scientist/medical examiner, psychological criminal profiler, and ballistics specialists). Much of the confusion and definitional misunderstanding of what criminology is stems from the different functions the individuals in these roles serve. Although each role is important in the fight against crime, some are not scientific at all and certainly not social science in practice or purpose. Although a surging social science today, criminology matured through an evolutionary process of shifts in primary focus, from philosophy to crime prevention/legal reform and then, ultimately, science.

The term *criminology* is attributed to the Frenchman Paul Topinard (1830–1911), who first used it during an 1889 anthropological study of criminality as a function of body types, a line of inquiry later made famous by William Sheldon's (1940) famous and controversial somatotype theory. Sheldon's politically incorrect biological thesis, that criminal propensity is predictable according to body shape and size classifications (endomorphs, mesomorphs, ectomorphs), is still debated in popular culture outlets such as the *New York Times* (Nagourney, 2008) and the social science arena (Maddan, Walker, & Miller, 2008). Although criminology may have originated around physiological foci, most early philosophers of crime were concerned with the functioning of the justice systems of the 18th and 19th centuries and much-needed legal reform.

Over time, criminology has increasingly come to be understood as the study of the causes, dispersion, and nature of crime, with theoretical criminology (i.e., the relating of crime to a plethora of individual, familial, community, and environmental factors known as *correlates of crime*) dominating the field (Vold, Bernard, & Snipes, 2002). The rise of theoretical criminology between the 1940s and today has proven both scientifically rewarding and limiting. On the reward side is a wide range of empirically valid theories that, however, are often criticized for lack of real-world utility. Nonetheless, theoretical criminology is the cornerstone of academic criminology, both historically and today, and is the core of a young discipline that is evolving toward greater pragmatism in terms of *applied criminology*. An applied criminology suggests that strategies and initiatives intended to prevent and lessen crime are informed by scientifically established theoretical

insights that are predictably capable of enhancing best practices within and around the criminal justice system.

The foremost pioneer of contemporary, and particularly American, criminology, Edwin Sutherland, offered what has proven to be a lasting definition, which is most often used to describe the field, in his seminal book *Principles of Criminology* (1939). According to Sutherland, criminology can be defined as follows:

[Criminology is] the body of knowledge regarding crime as a social phenomenon. It includes within its scope the processes of making laws, of breaking laws, and of reacting toward the breaking of laws. These processes are three aspects of a somewhat unified sequence of interactions. (p. 1)

It is interesting to note that whereas criminology is typically considered the study of the causes and nature of crime, and is often contrasted with *criminal justice*, which is concerned with the response to the problem of crime, Sutherland's famous definition clearly emphasized the significance of both. Consequently, criminology today is viewed somewhat dichotomously, with *theoretical* or *sociological criminology* denoting a focus on crime causation or the etiology of crime and *applied criminology* denoting work that is prevention, enforcement, or treatment oriented.

The Origins and Scientific Maturation of Criminology

Historical concern with crime is traceable to ancient Babylonia and the Code of Hammurabi, as well as biblical times, as evidenced by Old Testament dictates on restitution and the proportionality of punishment. Whereas such early edicts on infraction and punishment informed understanding of social control and justice, the origins of contemporary criminology stem from the Enlightenment period of the late 18th century, particularly the social and intellectual reforms then underway in western Europe. Philosophers from this period, such as Voltaire, Rousseau, and Locke, observed the superiority of reasoning based on direct experience and observation over subscription to faith and superstition that characterized collective opinion throughout the feudal era. Prior to this shift toward logic, crime was addressed informally within and between families whose recognition of justice was largely equated with realization of revenge (Larson, 1984).

The *family-revenge model of justice*, as observed in multigenerational feuds between Scottish clans, presented social-order maintenance and governing problems for feudal lords whose solutions were *trial by battle* and then *trial by ordeal*. Under trial by battle, either the victim or a member of the victim's family would fight the offender or a member of his or her family; under trial by ordeal, the accused was subjected to some "test" that would indicate guilt or innocence, such as running through a gauntlet or

4 • THE DISCIPLINE OF CRIMINOLOGY

being repeatedly dunked in water while bound by rope. Both approaches were vested in the spiritual notion of divine intervention. In battle, God would grant victory to the innocent side and likewise protect the falsely accused during trial by ordeal, as in the biblical report of protection afforded the prophet Daniel in the lions' den (J. M. Miller, Schreck, & Tewksbury, 2008).

Obviously, these methods failed to effect justice relative to a person's true guilt or innocence, instead yielding outcomes specific to a person's fighting ability, the capability to withstand various kinds of torture, or simply luck. The idea of being controlled by an evil spirit or that one's criminal behavior is attributable to the influence of the devil or some other "dark" force has long been a basis by which people have attempted to account for the unexplainable. Examples from early U.S. history include the Salem witch trials, wherein crime and deviance problems that could not be solved through actual facts and inquiry were attributed to witchcraft and demonic possession. The origins, for example, of "correctional" institutions in Philadelphia by Quakers who believed that isolation, labor, and Bible reading would result in repentance, reflect an early spiritually based form of rehabilitation. The term *penitentiary*, in fact, refers to institutions where society's crime problems were addressed through religious conversion and illustrates belief in spirituality as a source of and solution to crime. Although the Enlightenment period introduced a novel logic alternative to spiritual explanations, spirituality continued to affect interpretations of both crime causation and systems of justice for several centuries and is still relevant to current crime policy, as indicated by faith-based prevention and rehabilitation programming (Allen, 2003).

Although the Enlightenment period did not completely end the belief that spirituality affects crime, the momentum of experience-based reasoning led to a general view of social life and human behavior that served as a forerunner to criminology. One of the primary concepts from this era that was important for the development of criminology is the idea of the *social contract*. First introduced by Thomas Hobbes (1588–1679), the social contract involves the sacrifice of some personal freedom through internalization of law and endorsement of formal social control in exchange for protection and the benefit of all. For example, it is likely that either alone or with the aid of a friend you could forcibly take personal property, such as a wallet, purse, or textbook, from someone on an almost daily basis. Similarly, there is likely an individual or group that could forcibly take your property. Despite these obvious realities, everyone generally enjoys freedom of movement with peace and safety. By sacrificing your ability to take what you might from others, you are protected from similar victimization. This trade-off of loss of potential gain through limiting free will in exchange for law and order is an oversimplified example of the social contract (J. M. Miller et al., 2008).

As a result of the Enlightenment period, then, superstition- and spirituality-based orientations to crime were uprooted by

innovative ways of thinking that emphasized relationships between criminal behavior and punishment. This newer approach, exemplified in the writings of the Italian Cesare Beccaria (1738–1794) and the Englishman Jeremy Bentham (1748–1832), is known as the *classical school of criminology*, a perspective around which criminology would solidify and develop (Bierne, 1993). Notionally grounded in the concepts of deterrence and the dimensions of punishment (certainty, severity, and celerity), the classical school is significant for the development of criminological thought in at least two respects. First, crime was no longer believed to be a function of religion, superstition, or myth—views that largely placed the problem of crime beyond human control. Second, crime was seen as the result of free will. Viewing crime as a function of free will—in essence, as decision making—meant that it could now be explained as an outcome of rational choice. The ideation of rational thought (a calculation of gains vs. risks) suggests that crime is logically related to the elements impacting the decision to offend, such as the amount and relative value of criminal proceeds and the likelihood of detection, arrest, and conviction. The principles of the classical school, revised by legal reformers (neoclassicists) and now referred to as *rational choice theory*, continue to influence both the study of criminal behavior and the nature of formal social control as the criminal justice system continues in the attempt to achieve deterrence as one of its primary objectives (Paternoster & Brame, 1997).

Paradigm (i.e., model or school of thought) shifts are common to the history of all academic disciplines, and criminology is no exception. A new philosophy began emerging in Europe during the 19th century that first emphasized the application of the scientific method. This perspective, known as *positivism*, stressed the identification of patterns and consistencies in observable facts (Bryant, 1985). It was believed that, by examining known patterns, causes of behavior could be determined that would enable predictions about outcomes when certain conditions exist. For example, one can ascertain a pattern of comparatively high criminality in the lower socioeconomic class. Given the absence of other intervening factors, one can predict a rise in lower class criminality if a sharp increase in unemployment affects unskilled laborers. Regardless of whether this relationship is true, this line of thinking differs from the classical school's attention to free-will decision making, positing crime instead as a manifestation of factors external to and often beyond the control of individuals. Criminology did not move straight from a free-will orientation to endorsement of external influences; in between these perspectives was an era dominated by *determinism*.

Determinism takes the position that human behavior is caused by factors specific to the individual, such as biological and psychological traits. Perhaps the most famous figure associated with determinism in the context of criminality is Cesare Lombroso (1835–1909), whose "criminal type" illustrated in his influential work *Criminal Man*

(1863) suggests that some people, such as convicted murderer and notorious contract killer, who has been featured in several HBO documentaries, Richard “The Iceman” Kuklinski (1935–2006), are simply born criminals. Lombroso’s work, furthered by his student Raffaele Garofalo (1851–1934), was essential to viewing crime in a newer, more scientific light. As criminology continued to develop, determinism became more broadly viewed, with the inclusion of environmental and community criminogenic influences. In the evolution of American criminology, positivism began replacing the classical approach to crime during the 1920s, largely due to the rise of the Chicago School, a movement resulting from a series of seminal studies conducted by staff of the University of Chicago sociology department. From the 1920s through the 1940s, the Chicago School demonstrated that crime is largely a function of ecology, in particular the social disorganization that characterizes much of urban life.

The social ecological approach to crime is less concerned with the ways in which criminals and noncriminals differ in terms of intelligence, physical characteristics, or personality and more attentive to economic disadvantage, community cohesion, collective efficacy, and social stability. The Chicago School crime studies of Shaw and McKay (1942), Merton (1938), and Sutherland (1939) grounded U.S. criminology in sociology and established a dominant *paradigm*, or model of inquiry, oriented toward specifying environmental and community-level causes of crime and delinquency (e.g., Kornhauser, 1978). American criminology since its inception, then, has been conceptualized in theoretical terms—a perspective that has very much shaped its maturation. Although theory is vital to criminology in terms of justifying scientific status, confirmation of hypotheses (i.e., empirical proof) is also necessary and, as discussed in the next section, engaged through an intellectual process of *theory–methods symmetry*.

Theory: Methods Symmetry and Criminology’s Disciplinary Status

Science is the discovery of truths that comprise knowledge bases on particular topics. Determination of what is to be included or excluded in a knowledge base is a result of which ideas stand the test of scientific scrutiny, that is, which ideas are consistently observed in a systematic manner as factual according to real-world evidence. Accordingly, science is an outcome of theories (ideas) validated by research methods (empirical confirmation). Although leading criminological theories and many of the frequently employed research methods are treated in greater detail throughout the chapters in this book, the general nature of theory and its importance to criminology’s past, present, and future warrants a little more introductory discussion.

What exactly is *theory*? Perhaps the most concise definition of *theory* is simply “explanation.” Too often, theory is

erroneously thought of as philosophy or logic that has little relevance for real-world situations. In reality, theory is a part of everyday life, an attempt to make sense and order of events that are otherwise unexplainable. Think, for example, about the following common scenario. After dating for a long time, a college couple’s relationship is abruptly ended by one of the parties. Surprised and disturbed by this sudden and unwanted change, the rejected person will usually contemplate, often at great length with the counsel of friends, the reasons or causes leading to the outcome. Even if knowing *why* will not change the situation, we still want to know the reasons—the sole or set of causal factors—perhaps because making sense of seemingly random events reassures us that the social world is not chaotic and arbitrary. On a more pragmatic level, knowing why things happen enables us to modify our behavior or change relevant circumstances for a more preferable outcome in the future. In the case of criminology, the more fully we understand crime, its causes, and the evolution of criminal careers, the more ostensibly enhanced is our ability to prevent victimization and reduce crime rates.

Developing explanations for everyday events, then, is a common practice that entails identifying and weighing the relevance of potential causes and effects, which is a form of theoretical construction. Although theory is useful and commonplace in everyday life, academics often refer to scientific theory. Simply put, scientific theories are a means of explaining natural occurrences through statements about the relationships between observable phenomena. Observable phenomena are specified as either a cause or an effect and then positioned in a temporally ordered relationship statement. The causes and effects are termed *variables* (a *variable* is simply something that varies and is not constant). These formal statements, which are presented as *hypotheses*, are formed to explain or predict how some observable factor, or a combination of factors, is related to the phenomena being examined (in the context of criminology, some aspect of crime or social control). These relationships, which form specific theories of crime, are developed according to the logic of *variable analysis*. This analytic strategy specifies causal elements as *independent variables* and effects as *dependent variables*.

In criminology, not surprisingly, crime itself is the foremost dependent variable. It is imperative to note that the strategy of variable analysis is not interested in explaining crime per se; that is, the objective is not to explain what crime is in a definitional, policy, or legal sense. Instead, the variable analysis process seeks to account for *variation* in crime. Most theories conceptualize crime as a generic dichotomy, that is, the separation of phenomena into one of two categories. When crime is the dependent variable in a theory, further scrutiny usually reveals that theorists are actually referring to either *criminality* or *crime rate*. *Criminality* refers to the extent and frequency of offending by a societal group, such as the young, minorities, illegal immigrants, the unemployed, or people from a certain

region. *Crime rate*, on the other hand, refers to the level of crime in a location such as a city, county, or state. The focus on either criminality or crime rate is observable in the framing of different research questions: Why is there more homicide in Los Angeles than in San Antonio? Why are males more criminal than females? Again, the goal is not to explain or define the crime itself but rather to account for variability and fluctuation in criminality or crime rate across locales, social settings, groups, or over time.

After specifying causal and dependent variables, criminologists consider the nature of observed relationships to determine inference and possible implications. The information revealed from a theoretical proposition is interpreted by the condition of *correlation*: a *covariance* of factors or variables specified by the direction and strength of fluctuation in a dependent variable attributed to one or more independent variables. *Directional correlation* generally specifies either a positive or negative relationship. These terms do not mean the same thing as when used in everyday language. The expressions “My bank account is finally positive” and “She has a negative attitude” are value laden and indicate desirable and undesirable conditions. In the social sciences, a positive correlation more simply means that an independent variable and dependent variable fluctuate in the same direction, such as a group’s level of unemployment and involvement in criminal activity. A negative correlation indicates that independent and dependent variables covary in opposite directions, such as educational attainment and crime (with the obvious exception of white-collar offenses).

Consideration of the relationship between school grades and the status offense of truancy provides a clear illustration of directional correlation. Suppose a criminologist gathers data on both absences and grades from a large sample of randomly selected middle and high school students. If findings support the hypothesis that increased absences (the independent variable) bring about lower grades (the dependent variable), then a negative correlation exists, as would a decrease in absences be associated with academic improvement. In the latter scenario, the correlation, though negative in social science jargon, is the desirable outcome.

The strength of a correlation, on the other hand, specifies the degree of covariance between independent and dependent variables. For example, a gang prevention program delivered to an increased number of parents may effect only a minimal decrease in new gang affiliations. This relationship suggests an undesirable outcome, not because the correlation is negative but because the independent variable generated only little change in the dependent variable—perhaps because the parents of gang members are less likely to sincerely participate in an awareness program in the first place. The strength of a correlation is ascertained through statistical analysis, enabling the exact determination of covariance between variables as indicated by statistical significance parameters.

To analyze theoretical propositions, independent and dependent variables are transformed from a nominal or categorical to a measurable level, a conversion process known as *operationalization*. Operational definitions, then, enable empirical examination of cause-and-effect relationships by specifying measurable indicators for variables. How a variable is defined will affect the nature of a relationship and yield different (and possibly undesirable) implications for addressing crime. The following example of measuring recidivism demonstrates how important the measurement process is and how easily measurement error can occur.

Recidivism (repeat criminal offending) is one of the most common theoretically based dependent variables used in criminological research, especially as an effectiveness indicator for criminal justice prevention and enforcement programs. Depending on whether recidivism is being considered in a law enforcement, court, or correctional context (all three of which conduct deterrence and rehabilitation programs whose success is largely indicated by recidivism), the act of reoffending is likely to be operationally defined differently according to the immediate context. Repeat offenses are typically measured in law enforcement contexts as the rate of rearrest. Although it is seemingly natural and understandable that rearrest be used as a measure of police productivity, it falsely conveys the assumption that everyone who is rearrested will be convicted and thus potentially overestimates or exaggerates the perceived level of reoffending. Court-based operational definitions more accurately measure repeat offending as reconvictions, which is technically more consistent with legally determined official realities, but in correctional contexts reoffending is often calculated as reincarceration. Measuring reincarceration as an indicator of recidivism can also distort the true level of reoffending by not including convicted persons whose sanction did not include jail or prison time (J. M. Miller et al., 2008).

The strength and direction of correlations, then, serve the objective of determining *causation*, that is, whether the independent variable(s) prompt change in a dependent variable and, if so, in what manner. In order to have confidence in observed causal relationships, there must also be both specificity and accuracy in the measurement process, a methodological challenge in the study of a phenomenon that is inherently hidden, covert, and secretive.

Not all criminological research is engaged according to positivistic variable analysis toward the goal of establishing causal relations per statistical significance demonstration; instead, *subjectivism* exists as the foremost alternative philosophical paradigm in the social sciences. Subjectivists focus on discovery and description of the nature of criminal events; the social dynamics of group interaction in the specification and maintenance of criminal stereotypes and definitions; and the role of social forces, such as culture, that are not easily measured for variable analysis. Often referred to as *fieldwork* or *ethnography*, qualitative criminological research is vital to the overall criminological knowledge base because it enables

scientific attention to realities that cannot be measured because they are unknown (e.g., the population of prostitutes in a city) or are unreachable by traditional overt criminological research methods such as surveys or official data analysis. Some qualitative criminologists, known as *edge ethnographers*, go so far in the research endeavor as to place themselves in active criminal settings so as to observe first hand the immediacy of crime (Ferrell & Hamm, 1998; J. M. Miller & Tewksbury, 2001).

Criminology as Social Science

Numerous causal explanations that constitute theoretical criminology have been developed and tested; similarly, various research methods, both quantitative and qualitative, are regularly applied in the analysis of crime phenomena. Criminology thus offers, and is defined by, theory–methods symmetry to the practice of social inquiry. Characterizing theory as scientific means that inferential claims about relationships (the observed correlations) can be falsified. Research entails gathering data according to the operationalization process so that the theory is framed for systematic observation of cause and effect. The analysis and conclusions concerning the existence, nature, and implications of relationships are then compared with the conceptual logic of the theory itself. When observations are inconsistent with the basic premises of a theory, that theory is falsified. Observations that are consistent with a theory's statements about the relationship between cause-and-effect statements are customarily deemed more credible, but this does not mean the theory is necessarily true, because alternative theories might explain the same relationships.

Criminologists especially seek the answers to a wide range of research questions that focus on causality: Will increasing the severity of punishment lower the amount of crime in society? Do fines levied against the parents of truant children increase levels of parental responsibility and ultimately result in less truancy? Does a substance abuse treatment program in a correctional setting impact prisoners' rate of recidivism and drug relapse? These and similar questions reflect the desire to specify causal relationships that in turn may yield implications for criminal justice practice. Causation, in the context of scientific theorizing, requires demonstration of four main elements: (1) logical basis, (2) temporal order, (3) correlation, and (4) a lack of spuriousness. These are discussed in turn in the following paragraphs.

Scientific theory, just like any type of accurate explanation, requires sound reasoning. There must be a *logical basis* for believing that a causal relationship exists between observable phenomena. Criminologists are not concerned with offenders' hair or eye color when attempting to account for their behavior, for example, because there simply is no logical connection between these physical traits

and criminal behavior. A second necessary element for scientific theory construction is *temporal order*—that is, the time sequence of cause-and-effect elements. In short, causal factors must precede outcomes, as in the relationship between religious involvement and morality crime. Faith-based initiatives are vested in the belief that religious-based programs will better social conditions, including a reduction in crime. If offenders participate in religious programs (the independent variable) and subscribe to the convictions of religious doctrine condemning behavior such as gambling, commercial sex, and recreational substance use and abuse, then a reduction in their commission of these vice crimes (the dependent variable) would appear to be a causal relationship, because the religious programming both preceded and logically prompted the decreased involvement in the specified behaviors.

Correlation, as described earlier, is a third required element of a scientific theory. Correlation, again, indicates the presence of a relationship between observable phenomena and the nature of the relationship in terms of direction and strength. The last essential element for scientific theory development involves the condition of *spuriousness*. Most subcultures, for example, tend to be characterized by poverty, which confuses the causal relationship between subculture and crime in that it may be poverty that causes crime, and subcultures simply emerge within impoverished groups. Alternatively, it could be that cultural values encourage behavior manifested in both poverty and crime. Thus, the relationship among subculture, poverty, and crime is spurious, because cause and effect cannot be determined. Theorists, then, must frame relationship statements that reflect an absence of spuriousness. By adhering to these four axioms, criminologists increase the likelihood or probability that relationship statements are accurate.

Theoretical Praxis and the Future of Criminology

Although much of the criminological theory construction during the 1950s through the 1970s was basic research (the pursuit of knowledge for its own sake), criminologists came to observe that, once constructed and established, theoretical perspectives yield consequences, both intended and unintended, for criminals, victims, policymakers, and the general public. The idea of *theoretical praxis* (Shover, 1977) concerns not only the historical and cultural relativity but also, more importantly, the real-world impact of theories. Theories, once established, not only explain crime but also can significantly influence the behavior of both criminals and agents of social control.

The emergence of academic criminal justice during the 1970s has profoundly impacted criminology in both contrasting and complimentary ways. Given that criminology was primarily a specialty area within sociology and that

the bulk of social control and deviance research therein (e.g., theory construction and testing) was pure, no academic discipline was postured to address crime per se, a very real and pressing concern during the late 1960s and 1970s—a period of great social unrest characterized by a failing economy, civil rights controversies, and the Vietnam conflict. Through the Law Enforcement Assistance Administration Act, Congress sought to professionalize the criminal justice system with graduates of newly created “police science” and “penology” baccalaureate programs that were springing up around the nation. Established by the Omnibus Crime Control and Safe Streets Act of 1968 and abolished in 1982, the Law Enforcement Assistance Administration Act was a U.S. federal agency within the U.S. Justice Department that administered federal funding to state and local law enforcement agencies. Funding was provided for research, state planning agencies, local crime initiatives, and educational programs—the primary catalyst for what we know as criminal justice programs today (Morn, 1995).

Experientially based and rooted more so in public administration than social science, criminal justice programs originally focused on preparing students for practitioner and administrative careers in the prongs of the criminal justice system (policing, courts, and corrections) and were quickly dubbed a “professional” field—a somewhat pejorative term based on the atheoretical and thus unscientific nature of criminal justice. It is illogical to attempt to solve problems, social or otherwise, that have not been thoroughly defined or understood. Relatedly, the anti-crime suggestions offered by early criminal justice scientists were often based on what had proven successful in the past, with little or no concern for the scientific axioms discussed earlier. On the other hand, the most comprehensive knowledge base on crime is of little practical utility for social betterment without a real-world-applicable context.

For several decades, there has been tension between criminology and criminal justice that has witnessed the emergence of both criminology and criminal justice as independent fields of study. The future of criminology will no doubt remain rooted in theory construction and testing, but it is also obvious that increased attention will be devoted to developing best practices for policy based on these models. In this sense, criminology will likely continue to evolve from its theoretical origins, but in a manner more mindful of public policy. Whether criminology and criminal justice merge into a master discipline is doubtful, but theory will remain vital, for several reasons. It provides a scientific orientation to the phenomenon of crime, in which observations of facts are specified and classified as causes and effects. It grounds several styles of inquiry in the logic of systematic analysis. More important, the relationships between causes and effects can be identified, thus composing a knowledge base to guide decision making and planning concerning how to best address the problems presented by crime. Criminological

theorizing is increasingly generating practice and policy implications and, as such, bolsters and is an integral part of applied research. Even the pure theorists, who may have no particular interest in addressing a specific crime or delinquency issue, may generate the knowledge necessary for others to modify the criminal justice system’s efforts. There is, then, a connection between theory and policy reflected in the increasing multidisciplinary of contemporary criminology that is likely to be a major force in the future of the discipline.

HISTORY AND EVOLUTION OF CRIMINOLOGY

CHARLES F. WELLFORD

University of Maryland

This chapter discusses the origins and development of the discipline of criminology and addresses the questions of where criminology is today and where it is going. In large part, criminology is a history of the ideas that have informed the evolution of criminology and that stand as the intellectual foundation of one of the fastest growing academic disciplines of the last 40 years.¹

No history of criminology can ignore the political forces that impact any attempt to address a set of behaviors that stir so much public concern. Although all science is subject to such influences, it is important to recognize that the object of criminological study, more than most social phenomena, produces public images of crime and criminals and ways to respond to them that can constrain and influence their study. Therefore, a history of criminology must also consider the external influences that have affected its development. As these issues are addressed, the internal dynamics of the discipline as well as the external forces that have sometimes changed the course of criminology and its focus are examined.

Any intellectual history is, in part, informed by where we understand ourselves to be today. Today, criminology finds itself defined by three major themes: (1) the steady movement toward a more rigorous science, (2) a commitment to rigorously tested theories of crime and criminal behavior, and (3) the establishment of a demand for evidence-based crime control and justice assurance policies and practices. This was perhaps best expressed by Edwin Sutherland (1934), who defined *criminology* as

the study of the making of law, the breaking of law, and the reaction of society to lawbreaking. However, this is not always how criminology understood its scope. So let us return to one beginning before we consider the beginning that is now defined as the foundation for our field.

Two Points of Departure for the Beginning of Criminology

The Classical School of Criminology

In 1764, an obscure Italian lawyer published a book that was soon to remove his obscurity and become one of the most influential legal treatises of the 18th century. The author was Cesare Beccaria, and the book was *Essays on Crime and Punishment*² (hereinafter referred to as *Essays*; Beccaria, 1764/1963). Influenced by the Enlightenment philosophers, Beccaria sought to reform the criminal justice system to make it more humane and fair. He argued for punishments other than corporal punishment and death by embedding punishment in an enlightened legal system. Within 10 years of its publication, the book was translated into all European languages, and Beccaria was celebrated as a profound new legal thinker; the work also influenced the governments of numerous countries, including England and the United States. As early as 1775, John Adams referenced *Essays* in his justification for accepting the unpopular and politically dangerous task of defending the British soldiers who fired on

the citizens of Boston who charged the arms depot atop Bunker Hill. Adams (quoted in McCullough, 2001), in explaining this decision, quoted the following from Beccaria:

If, by supporting the rights of mankind, and the invincible truth, I shall contribute to save from the agonies of death one unfortunate victim of tyranny, or of ignorance, equally fatal, his blessing and years of transport will be sufficient consolation to me for the contempt of all mankind.

Essays challenged the traditional notion that the foundation of the legal system was religion and that the cause of crime was falling from grace (the devil). Instead, Beccaria (1764/1973) offered the notion that crime was a result of choice (the operation of free will) and that crime was selected when the rewards of crime exceeded the pains resulting from the commission of crime. It is obvious that Beccaria, influenced by the moral calculus of Jeremy Bentham (1789), saw crime as a choice, not a compulsion. From this central idea he built a system of justice that specified that punishments should fit the crime (just enough punishment to offset the pleasure of the crime); that punishment was most effective when it was swift and sure but not overly severe; that confessions could not be coerced; and that the death penalty was not warranted, because it was not reversible in the case of error, and no one would agree to the state taking his life if he had a choice. In a series of interrelated chapters, Beccaria described a system of justice that soon became the model for democracies around the world.

As a legal philosopher, Beccaria subscribed to the idea that government exists at the will of the people and that, as such, the laws should restrict freedom only to the degree necessary to guarantee order and freedom. With this foundation, societies establish governments and laws to expand freedom, not to ensure the interests of one group above another. The drafters of the U.S. Constitution were greatly influenced by Beccaria; the sections of the Bill of Rights that address crime and justice in particular reflect his principles and guidelines.

Beccaria also argued that the setting of punishments (the balancing of pleasure and pain) should be done with “geometric precision,” suggesting that the emerging ideas of science and the scientific method should be used to structure the justice system. Although he was not educated in science, his work reflected the growing role of science in all aspects of social life. The science of criminal justice was fully anticipated in his approach to structuring a fair system of laws and justice. Finally, Beccaria knew how dangerous it was to write a treatise that challenged the conventional wisdom that law came from God and that rulers were God’s representatives on earth. As he sought to mitigate the subversiveness of his arguments, Beccaria noted that he was not challenging the church or church law but was simply offering a model for reform of criminal law and justice that was consistent with teachings of the church and the interests of the state. Beccaria clearly understood the tensions between a science of crime and justice and a system of laws and justice that reflected interests and power. Although he

called for the former, he recognized the danger in doing so and sought to avoid the pain that others had suffered who challenged the positions of those in power.

So, some refer to Beccaria as the father of the *classical school of criminology*, the first school of criminological thought. Notice, however, that this approach to defining criminology has as its primary focus the criminal justice system. The theory of criminal behavior in this school is free will, and the definition of *crime* is behaviors prohibited by the state and punished by the state. Readers will see a very different set of assumptions and foci when the discussion turns to the creation of criminology as an academic field of study. This approach pays little attention to the criminal justice system and focuses almost exclusively on the causes of crime.

The Causes of Crime

In 1876, another Italian, this time a physician, published a book that was to transform how we think about criminals. Cesare Lombroso wrote *Criminal Man*, in which he reported on his observations of criminals while working as a doctor at a local prison. In the first edition of this work (only 252 pages in length), he observed that criminals had physical characteristics that more closely resembled animals lower in the evolutionary chain than man. Writing just 17 years after Darwin’s (1859) *On the Origin of Species*, which introduced the notion of evolution into scientific and popular thinking, Lombroso explained crime as the behavior of humans who were “throwbacks” to earlier developmental forms. Their physical appearance signaled their inferior intellectual and moral development. Crime was a product of this inferior development. For 30 years, the biological causes of crime heavily influenced thinking about crime causation.³ The most forceful rejection of this particular approach to crime causation came with the publication of a large-scale empirical test of it, *The English Convict* (Goring, 1913/1972). The author, Charles Goring, using the emerging statistical techniques that now form the basis of social science empirical research, tested convicts and nonconvicts and demonstrated that the physical differences that Lombroso described did not differentiate between these groups. In fact, by the time this work was published, Lombroso had published the fifth edition of his book, with each edition getting longer and noting other possible explanations of crime (the fifth edition had grown to 1,903 pages and listed hundreds of causes of crime).

Criminology Emerges as a Named Field of Study

The 1800s saw the emergence and growth of the science and the establishment of separate disciplines and research areas. Prior to this time, all sciences were included in faculties of philosophy. It was in the early 1800s that sociology was named and textbooks began to emerge (Spencer, 1874; Ward, 1883), and in 1905, the American Society of Sociology was formed. National organizations promoting

medicine (1847), history (1884), chemistry (1875), physics (1899), psychology (1892), and economics (1885) emerged in the later part of the 19th century as these new sciences became part of universities and public discourse. Criminology had a longer period of formation. In 1885, Raffaele Garofalo (a student of Lombroso) published *Criminology*, in which he used the word *criminology* to refer to the science of explaining crime (Garofalo, 1885/1968). A series of books written in the late 1800s established criminology as a field of study, but, unlike other social sciences, this did not become reflected in the structure of disciplines in universities; neither did national or international organizations emerge to promote this field of social science. It would not be until the 1940s that these signs of a new science of crime and justice would emerge (the American Society of Criminology was founded as an association of police professors in 1941, and the first American School of Criminology was opened in 1950 at the University of California, Berkeley). What happened during this 50-year period between the time criminology was recognized as a field of study and it became organized professionally and in universities? The answer to this question requires us to explore how explanations of crime developed after Lombroso and how Beccaria became central to the new field of criminology.

The Development of Criminological Theories of Crime

For almost two centuries after Beccaria's (1764/1963) work, criminologists did not pay consistent and organized attention to the criminal justice system; instead, the tradition of criminology begun by Lombroso—the search for the causes of crime—was the focus of criminology until the last half of the 20th century. This period of search for the causes of crime passed through four distinct phases of theoretical development:⁴ (1) single-factor reductionism, (2) systemic reductionism, (3) multidisciplinary theories, and (4) interdisciplinary theory. Today, interdisciplinary theory stands as the dominant model for explaining crime (and other human behaviors). Criminology today rests on two foundations: (1) the interdisciplinary explanation of crime and (2) the analysis of the fairness and effectiveness of the criminal justice system. Both of these fundamental aspects of criminology are informed by (as Beccaria [1764/1963], Lombroso [1876], and Sutherland [1939] had called for) by the application of scientific methods.

Single-Factor Reductionism

In its initial formulation, Lombroso (1876) argued that all crime could be explained by one factor: a failure of evolution. No other variable or dimension needed to be considered to understand the range of crimes and/or the types of criminals. The theory was parsimonious to the extreme; this single factor could explain crime. Soon, others began to identify other

single-factor explanations for crime: Mental illness (or, as it was called then, “feeble-mindedness”; Dugdale, 1877), bad families, the loss of faith or religion, and other explanations were offered not as parts of a comprehensive explanation but as the explanation of crime—with all influences reduced to this one factor. This approach quickly collapsed as the study of persons who committed crime began to identify a wide range of characteristics that appeared to distinguish criminals from noncriminals.⁵ This led to the next two approaches to developing theories of criminal behavior: (1) systemic reductionism and (2) multidisciplinary approaches. Although they occurred simultaneously, the greater influence was made by systemic reductionism, for reasons now discussed.

Systemic Reductionism

As noted earlier, there was a period of over 50 years between the time when criminology emerged as a field of study and when it was institutionalized in universities and with its own professional organizations. During this period, in the United States,⁶ criminology was contained in almost all instances in sociology departments. As such, during this period the explanation of crime causation was constrained by the sociological system of knowledge. Systemic reductionism (i.e., explaining a phenomenon from a singular knowledge system or discipline perspective) expanded beyond sociology, but it was the sociological perspective that dominated criminological theory for many years and even today is the dominant theoretical perspective. The importance of systemic reductionism can be seen in many criminological textbooks that organize the discussion of crime causation into a series of sections—sociological explanations, psychological explanations, and biological explanations—each presented as if these systems of knowledge were unrelated to each other and each providing competing ways of explaining crime.

Why did this capture of the study of crime by sociology, which all the early thinkers recognized as having a multitude of explanations, occur? Most likely it occurred because of the way sociology developed at the University of Chicago, the birthplace of American sociology. Here, sociology (the Chicago School) was the study of urban development and the problems associated with such development. It made perfect sense to locate the study of crime in such a field of study and, once located, it is not surprising that the theories that came to dominate criminology were sociological in nature. The biology and psychology of crime were greatly minimized, and instead crime was seen as a function of community, family, school, and the other socializing institutions. The explanation of crime became the explanation of crime rate differences within the city, across class levels, and between recent immigrants and less recent immigrants. Criminals were disproportionately found in poverty and in homes and friendships that saw criminal behavior as a reasonable response to their social location. As Dennis Wrong (1961) observed near the end of this period of theory in criminology, the sociological

systemic reductionism presented an “oversocialized conception” of human behavior that largely ignored personality and biology.

This is not to suggest that this period made no contributions to understanding crime. The focus on variation in crime rates introduced issues of critical importance to understanding crime. The development of theories such as *differential association* (Sutherland, 1934, which offered a social learning explanation), *anomie* (Merton, 1938, which explained crime concentrations in the lower class as a result of a cultural condition), *culture conflict* (Sellin, 1934, which suggested that crime clustered in groups going through a transition from one culture to another), *social disorganization* (Shaw & McKay, 1942, which explained crime in poor areas as a result of the relative absence of family and community controls on behavior), and *labeling* (Schur, 1971, which argued for the criminogenic effect of designating people as criminals) have proven to be valuable in the development of more comprehensive theories of crime and theory-based crime interventions. All of these approaches persist today in only slightly modified forms or as the parts of more complex explanations. The essential element in sociological systemic reductionism is that crime is clustered in the lower class, and therefore there is something in this social situation that accounts for the higher rates of crime. According to systemic reductionism, the individual offender was considered a reflection of his or her social situation.

Multidisciplinary Approaches

Of course, sociologists were not the only ones interested in the causes of crime. While sociology was dominating the study of crime in universities, psychologists, biologists, and others were considering how their disciplines or theoretical perspectives would explain such behavior. Furthermore, it became clear that these other perspectives offered reasonable approaches as well as some research that demonstrated that the approach had some level of empirical support. Gradually, a model of crime explanation emerged that is still with us today, especially in standard criminological texts: the *multidisciplinary explanation* of criminal behavior. This approach argues that people become criminals because of a set of explanations drawn from all of the social and behavioral sciences, including biology, psychology, anthropology, economics, and sociology. Only by using all of these perspectives can one understand criminal behavior. This can be seen in contemporary criminological texts that have separate chapters on each of these approaches to explaining crime. Of course, multidisciplinary approaches are not theories at all, but instead are the search for the set of causal variables that explain the greatest amount of variation in the occurrence of criminal behavior.

The most prominent practitioners of multidisciplinary criminology were Sheldon and Eleanor Glueck. In a series of longitudinal studies they sought to find the factors that “unraveled” juvenile delinquency and adult criminal behavior.

Sheldon Glueck was a lawyer with little advanced education in the social and behavioral sciences. Although Eleanor had that education, it was Sheldon who formulated their approach to research and theory. Working in a law school setting, they pursued an empirically based way to predict and explain criminal law violations of juveniles and adults. The Gluecks made a particularly clear statement of their position and their rejection of systemic reductionism:

It is common knowledge that the great majority of children growing up in urban slums do not become delinquents despite the depravations of a vicious environment, despite the fact that they and their parents have not had access to fruitful economic opportunities, despite the fact that they are swimming around in the same antisocial subculture in which delinquents and gang members are said to thrive. Why? (Glueck & Glueck, 1968, p. 25)

The Gluecks’s position was that the then-dominant sociological approach could not explain the empirical reality that most of the individuals who grow up in high-crime areas are not criminal. Their focus was on explaining why a few in those areas became, and in some cases remained for many years, offenders while others did not. To answer this question, they sought to find out what distinguished the law violator from the non-law violator when both came from the same deprived social conditions. To do this they studied similarly socially situated individuals, looking for shared characteristics that distinguished them. Drawing on what they considered the best possible sources of explanation, they considered biological factors (e.g., body type), psychological differences, family structure, parent behavior differences, and school factors to predict and understand the occurrence of delinquent and criminal behaviors. In all of their works the Gluecks sought to identify the specific set of factors that accounted for the fact that individuals faced with the same difficult social conditions would behave differently.

Sheldon and Eleanor Glueck sought to move the study of criminal behavior out of the sole domain of sociology and make it at least multidisciplinary. They did this by showing the empirical relationship between criminal behavior and a number of factors drawn from a variety of disciplines and perspectives. However, their work did not produce a coherent theory of crime that went beyond their empirical results—it did produce a widely used (for a time) scale to predict delinquency and focus prevention and intervention efforts, and it did force criminologists to begin to recognize that disciplines other than sociology would be needed to develop a comprehensive explanation of the criminal behavior of individuals.

Interdisciplinary Explanations

Criminology as a separate field of study emerges when the model underlying the explanation of criminal behavior becomes interdisciplinary. Only then does an intellectual justification for a separate field of study in universities

exist that is compelling enough to support such a development. Today, the leading journal in criminology—the *Journal of the American Society of Criminology*—has as its subtitle *An Interdisciplinary Journal*; a clear statement of the importance of this perspective to criminology.

What, however, is meant by *interdisciplinary theory*? Most obviously, this approach assumes that more than one discipline is needed to explain criminal behavior. Any approach to explanation that is built on one discipline is by definition incomplete. However, if we have only explanations based on the accumulation of variables from different disciplines, then we have what the Gluecks proposed: multidisciplinary explanations. So, an interdisciplinary theory goes beyond the assembly of contributions of different disciplines and integrates the contributions of these different disciplines into a coherent theory of criminal behavior. This approach emphasizes bringing perspectives together, not the competition of perspectives to see which one is “right.”

Interdisciplinary theory assumes there is a role for biological, psychological, social, and cultural explanations but that the relationships among these perspectives is as important and that no perspective can totally explain the influence of another perspective. Thus, interdisciplinary theory can be expected not only to contain elements of all of the explanatory perspectives but also to go beyond that to identify how each level of explanation influences, but does not eliminate, each other level of explanation. For example, the question is not whether nature or nurture causes crime but rather how they interact to account for individual variations in criminal behavior. It is not a question of why does poverty seem to be associated with higher crime rates but rather how do individual development and poverty interact to explain why some people are delinquent and others are not. Each dimension of explanation is to a degree irreducible, and each is related to and influences the other.

One of the most influential theories in criminology today is *developmental or life course theories*.⁷ These are good examples of how interdisciplinary theory is emerging as the dominant paradigm in the field. Robert Sampson (2001) suggested that this approach to theory is “best introduced by considering the questions it asks,” which he identifies as including the following:

- Why and when do most juveniles stop offending?
- What factors explain desistance from crime and delinquency?
- Are some delinquents destined to become persistent criminals in adulthood?
- Is there, in fact, such a thing as a life–course-persistent offender?
- What explains the stability of offending?

One of the early contributors to this approach, Terrie Moffitt (2001), addressed these questions by hypothesizing that there were two patterns of antisocial behavior: (1) *life course persistent*, in which the offender started early and maintained his or her involvement in antisocial behavior

throughout the life course, and (2) *adolescent limited*, in which the offender’s antisocial behavior emerges and ends during that period of the life course. Moffitt observed that the persistent pattern results from “childhood neuropsychological problems interacting cumulatively with their criminogenic environments producing a pathological personality” (p. 92), whereas the adolescent limited pattern is the result of “a contemporary maturity gap [that] encourages teens to mimic antisocial behavior in ways that are normative and adjustive” (p. 93). Biology, psychology, and social levels of explanation clearly are evident even in this summary statement of her work. This is characteristic of efforts to answer the questions posed by Sampson (2001) and is a central characteristic of life course theory. For this reason, this approach offers a framework for criminology to move closer to an interdisciplinary theory of criminal behavior that will more fully justify the emergence of the field as a new discipline in the social and behavioral sciences.

Criminology Emerges as a Separate Field of Study

The emergence of criminology as a separate academic and research field is an issue discussed earlier in this chapter. This occurred at two universities: the University of California at Berkeley and Michigan State University. Neither focused on what had occupied criminologists for over 60 years: the explanation of criminal behavior; instead, both emerged to address the issue of the need for better educated police officers.

The effort at the University of California was led by the now-legendary figure in American policing, August Vollmer. Albert Morris (1975), in his history of the American Society of Criminology, described Vollmer as follows:

Probably the most widely known and most innovative police chief in American police history, August Vollmer (1876–1955) had been Marshal of Berkeley (1905–1909), the first Police Chief of Berkeley (1909–1932), and Professor of Police Administration at the University of California at Berkeley (1932–1937), and was widely sought as a consultant in police administration. He was physically an imposing person (6’4” tall and weighing about 190 lbs.) who always seemed to be in top physical condition. He was a broadly informed and creative man with a contagious enthusiasm for making police work a profession, with a highly trained core of persons who had college degrees and who could teach at the college level. As early as 1916, Vollmer, in collaboration with law professor Alexander Marsden Kidd, developed a summer session program in criminology at the Berkeley campus in which courses were given from 1916 to 1931, with the exception of the 1927 session. (p. 32)

Vollmer taught courses at Berkeley, helped form a major offered in political science at Berkeley in the middle 1930s, joined the faculty in 1932, and led the development of first School of Criminology in the United States founded at

Berkeley in 1950. For Vollmer, the primary purpose of his efforts was to educate police officers who could lead the professionalization of policing. It was Vollmer who in 1941 convened a meeting at his home that led to the creation of the National Association of College Police Training Officials, which later became the Society for the Advancement of Criminology and is today the American Society of Criminology. The purpose of the organization and the academic programs that participated in its founding was stated as follows (Morris, 1975):

1. To associate officials engaged in professional police training at the college level
2. To standardize the various police training curricula
3. To standardize, insofar as possible, the subject matter of similar courses in the various schools
4. To keep abreast of recent developments and to foster research
5. To disseminate information
6. To elevate standards of police service
7. To stimulate the formation of police training schools in colleges throughout the nation

As an academic enterprise at Berkeley, criminology began with a focus on the criminal justice system and, more specifically, the training of police.

The story at Michigan State University was similar. Founded in 1935, the School of Criminal Justice is the program with the longest history of continuous degree granting in the field. Led by the efforts of LeMoyné Snyder (a doctor and son of a former president of Michigan State) and in cooperation with the Michigan State Patrol, the university approved a new department and major in 1935 that was to educate current and potential police officers in administration and law. As stated in 1935 (Brandstetter, 1989), the new dean of the program summarized it as follows:

The graduates of the course be, first of all, well-trained college men with fundamental training in English and the sciences—both physical and social. That over-specialization be avoided in the first three years of training. That students be given instruction in criminal law and evidence. That the third year of training be given to a general survey in police science and administration. That after approximately three years of training at the college, intensive training at the State Police—along special lines for which his earlier training has fitted him. That four years of military science be required so the student may become trained in military discipline. (Brandstetter, 1989)

Educated police were the goal of the program. The professionalization of policing was the ultimate goal of the effort. As an academic enterprise, criminology emerged with a much closer connection to the goals of Beccaria than it did to the goals of Lombroso. The tension between training and education is clear in both programs, but the focus on education in the Michigan State program set the standard for all academic programs that followed.

While the professional organization for criminology was changing from a focus on policing, the new field of

criminology was also changing. When the program at Florida State University was formed in the 1950s, it covered causes of crime, policing, corrections, and criminal law, with an emphasis on science and research as a comprehensive criminology program that would serve as a model for others throughout the country. In 1957, the professional organization changed its name again to the American Society of Criminology, to reflect the growing breadth of the field and the organization.

So, criminology began at two state universities in the 1930s, and by the 1950s was emerging at other, predominantly public, universities. In 20 years, it has changed from police education to a new field that includes the two great traditions of criminology: (1) a concern with the causes of crime and the improvement of the criminal justice system and (2) a reliance on science as the method to understand causes and identify improvements. Still, the field had not yet fully found its identity. Note that Berkeley's program is a School of Criminology, Michigan State's is a School of Criminal Justice, and Florida State's also is a School of Criminology. In the 1970s and 1980s, the model program was at Albany University, the School of Criminal Justice, whereas in the 1990s and 2000s, the most prominent program has been the University of Maryland's Department of Criminology and Criminal Justice. Although the names differ, a look at their programs, research, careers of graduates, and faculty reveals much similarity. Why, then, do the programs have different names?

In the 1960s, crime became a focus of national attention and federal legislation and funding. The goal was to reduce crime through more effective criminal justice. For some people in the political world, criminology was associated with causation ("root causes"), treatment of offenders, and being "soft" on crime. This position was enhanced when the School of Criminology at the University of California at Berkeley became a center for radical, left criminology and was closed by the university. As the field grew, in part fueled by the growing national interest in crime and federal funding, *criminal justice* became a more acceptable name than *criminology*. However, as the field matured and the role of criminology became clearer, the use of the name *criminology and criminal justice* emerged as a clear statement that the field addressed both foundations of the field—causes of crime and criminal justice improvements. Now Beccaria and Lombroso could be seen as the founders of a field that lived up to Sutherland's (1939) definition of a body that scientifically studied the making of law, the breaking of law, and society's reaction to lawbreaking. Today, even a brief perusal of the program of the meetings of the American Society of Criminology reveals that the field encompasses just about every aspect of crime and justice but always with a concern for the scientific rigor of the enterprise.

The Making of Law

Although Beccaria had a clearly formulated theory of lawmaking, we have not seen much concern with this topic

in this account of the development of criminology. Whereas the theory of law has not been a focus of criminology, the making of law has been. Criminology in all of its primary forms is concerned with lawbreaking. However, we know that criminal law is not a scientific concept; instead, it is a legal or political creation. No other science is like criminology in that its basic object of study is defined external to the field of study. Legislatures do not define elements of the atom, groups, interactions, or economic behavior, but they do define crime and those definitions vary through time and space. To some people this means that a science of criminology is not possible; to others, it simply defines another set of issues for criminology to address, including “What is crime?” Three distinct approaches to answering this question are found in the history of criminology: (1) legalistic, (2) sociological, and (3) social legal.

During most of the time that the field of criminology was being developed, people assumed that crime was behavior that had been judged to be a violation of the criminal law—the legalistic approach. This was perhaps most clearly expressed by Paul Tappan (1947) when he observed that “Crime is an intentional act in violation of the criminal law (statutory and case law), committed without defense or excuse, and penalized by the state as a felony or misdemeanor” (p. 12). Related to this approach to defining crime is the position that the criminal is only known when a “duly constituted authority of the state” (Tappan, 1947) determines that the person has violated the law. Only when convicted is a person a criminal. Thus, any behavior that was prohibited by statute and judged to have occurred by a duly constituted authority was deemed a crime and the object of criminological study. Obviously, in this approach crime is empirically easy to measure but suffers from the relativity of the criminal law and the operation of the criminal justice system. Explanations of crime would have to be relative to the legal system and historical period and could not have the standing of scientific (i.e., universal) explanations.

During the period when sociology dominated criminology, another approach was suggested that was thought to avoid the political and relative nature of criminal law—the sociological approach. Most clearly articulated by Thorsten Sellin (1938), the approach suggests that criminology should broaden its scope and consider all conduct norm violations. Sellin observed that “confinement to the study of crime and criminals and the acceptance of categories of specific forms of crime and criminal as laid down in law renders criminological research invalid from the point of view of science” (p. 4). He suggested that instead criminologists should seek to understand any variation from normative behavior. Although this approach avoided the political nature of law, it introduced an even more relative dependent variable for the field and all but eliminated the connection between studies of causation and crime prevention and control. Needless to say, this approach has not been widely followed in criminology.

The social legal approach offers a way to avoid the problems of the other two approaches to defining crime and the object of criminological study. It begins with the observation that some behaviors must be controlled by the state if society is to function and exist. Killing, sexually and otherwise assaulting, and stealing between citizens must be controlled if a society is to exist. Edwin Lemert (1972) observed the following:

Human interaction always occurs within limits: biological, psychological, ecological, technological, and organizational. These explain why certain general kinds of behavior are more likely to be deemed undesirable than others. Practically all societies in varying degrees and ways disapprove of incest, adultery, promiscuity, cruelty to children, laziness, disrespect for parents and elders, murder, rape, theft, lying and cheating . . . certain kinds of actions are likely to be judged deleterious in any context . . . It is not so much that these violate rules, it is that they destroy, downgrade, or jeopardize values universal in nature. (p. 5)

Thus, criminal laws can be divided into at least two categories: (1) those that seek to control behaviors that must be controlled if the society is to exist (e.g., homicide) and (2) those whose regulation reflects the values and political decisions at a certain place and time (e.g., drug offenses). Criminologists are not terribly concerned with the origins of the former, but they are very much interested in understanding why other behaviors are criminalized and whether criminalizing these behaviors contributes to more or less crime. Connected to social legal approach to the definition of crime is the contention that the best way to measure crime and criminals is by direct observation or questioning. You do not rely on the criminal justice system to measure the level of crime (e.g., from reports to police) but instead ask the public directly about their experiences with crime (e.g., victimization studies). Similarly, you do not determine who is criminal by the operation of the criminal justice system (e.g., arrest or conviction) but instead by seeking direct evidence of the behavior (e.g., self-report studies). This is particularly important to the task of studying the differential application of the law to segments of the population. What is labeled here the *social legal approach* to law and crime is the dominant view in criminology today, although much criminological research violates this perspective and accepts the easier means of measurement: official data.

The Future of Criminology and Criminal Justice

During the past 40 years, criminology has emerged as one of the most dynamic social sciences and certainly the fastest growing. Today, it stands on clear foundations of commitment to scientific rigor, interdisciplinary theory of crime, and improving the operation and “justness” of the criminal justice system. It stands firmly on the shoulders

of many individuals, most importantly Beccaria and Lombroso. Although federal funding for criminological research has diminished in recent years, there is every reason to believe that it will increase as the role of criminology in preventing and controlling crime through theory and evidence-based approaches becomes more widely known and appreciated.

Few major initiatives in criminal law and criminal justice during this period have been developed without significant criminological involvement. Hot-spots policing, problem-oriented policing, crime mapping and analysis, sentencing guidelines, specialized courts, sex offender programming, effective models of rehabilitation, reentry programs, problems of eyewitness identifications, procedures for police lineups and interrogations, the role of DNA in courts and policing—the list goes on and on. The point is that criminology is making a difference. As long as it continues to be rigorous in methods, interdisciplinary in approach, and guided by a commitment to justice, it will flourish and continue its emergence as a vital scientific enterprise.

Notes

1. Between 1970 and today, it is estimated that enrollment in criminology programs at universities in the United States has increased by a factor of 1,000, partly because of the rapid growth in the number of such programs.

2. He was the primary author, but contemporary scholarship suggests that others were intimately involved in the development and writing of the book. Although that is not critical for this chapter, readers can find a discussion of this in the foreword to the Paolucci edition (Beccaria, 1764/1963).

3. For a discussion of this criminological work during this period see Vold (1979), especially Chapters 3 and 4.

4. Although these themes were dominant during specific times, the development of theories of crime has not been so straightforward or developmental. In fact, all four approaches to explaining the causes of crime can still be found today.

5. This approach continues today in some public and political discourse. Too frequently we hear that crime is caused by welfare moms, lead paint, unemployment, and a variety of other factors. While criminologists widely acknowledge the multifaceted nature of crime causation, the problem is that we do not know which cause is most important or how multiple factors interact. This type of response reinforces the idea held by some that criminologists do not know much about crime.

6. In Europe and the rest of the world, criminology did not develop as rapidly as it did in the United States. In many ways, the history of criminology since the beginning of the 20th century until quite recently has been written in the United States.

7. As noted earlier, criminological theories do not easily disappear. The problem has been that these theories accumulate but are not cumulative. The issue being addressed today in criminology

is how to use an interdisciplinary framework to integrate these theories and develop cumulative knowledge.

CRIMINOLOGY AND PUBLIC POLICY

TODD R. CLEAR

John Jay College of Criminal Justice

NATASHA A. FROST

Northeastern University

Criminology would seem to have a natural connection to public policy. Many, if not most, of the questions that criminologists seek to answer directly or indirectly impact questions of public policy. Criminologists seek to understand the nature and extent of crime, to explain why people commit crime, and to advance knowledge as to how crime might be prevented. Policy-makers seek to address an array of social problems, including the problem of crime. Despite this seemingly natural connection, the field of criminology has had an uneasy relationship with public policy and has had somewhat less of a direct effect on matters of public policy than some might expect.

There have been some notable instances in which criminological research has impacted public policy. For example, Lawrence Sherman's randomized field study in Minneapolis (often referred to as the *Minnesota Domestic Violence Study*), which focused on policing domestic violence, led to widespread reforms in the way that police departments responded to domestic violence calls (Sherman et al., 1999). The work of George Kelling and his colleagues as they developed the "broken windows" model of policing similarly led to important changes in police strategies, first in New York City and later in other major jurisdictions. More recently, the research of Joan Petersilia (2008) has led to the adoption of "earned discharge" parole in California. Although there are a number of instances in which criminological work has directly

impacted policy, much of the policy-relevant criminological research has had little to no measurable effect on public policy. This lack of effect can be attributed in part to the reluctance among some academics to engage directly in the policy arena. In a provocative essay lamenting criminology's irrelevance, James Austin (2003) argued that "in terms of having any effect on criminal justice policy, there is little evidence that any criminologist's career has made much of a difference" (p. 558).

Although criminology's policy impact has been largely inconsequential to date, there have been renewed calls for a policy-oriented approach in criminology. Leading criminologist Ronald Clarke (2004) proposed that the field of criminology be reconfigured as a field of "crime science" that has as its main focus studying crime in ways that inform policy. Prominent criminological theorists David Garland and Richard Sparks (2000) suggested that the coming generation of criminology be one that takes the problem of crime as a serious concern, with a renewed commitment to reducing the impact of crime on everyday lives.

The Emergence of Criminology

Criminology began as a theoretically oriented field of study. Notably, the early criminologists were drawn from various disciplines (sociology, psychology, medicine) and

would likely not have self-identified as “criminologists.” Nonetheless, early writers about the social science of crime, such as Émile Durkheim (in the field of sociology), sought to explain the existence of crime in society. Durkheim and others also set out to explain patterns of crime through the examination of crime across time and place. Shortly afterward, writers sought to explain *why* some people engaged in crime when others did not. In the late 1800s, Cesare Lombroso, who is often referred to as the “founder of modern criminology,” launched the science of criminology through his explorations into differences between criminal and noncriminal populations. As Lombroso’s biological explanations for criminal offending waned in popularity, the Chicago School, with its ecological approach to the study of crime (and related social problems) emerged as the dominant paradigm in the 1930s and remains influential today. Between the 1930s and today, the field has experienced a proliferation of theories of crime, such that an entire college semester is no longer enough time to adequately address all of the theories that have been advanced to date. There is no one, uniform theory of crime; instead, there are multiple and competing theories. For most of criminology’s history, developing and testing these theories has been the focus of the field.

Throughout its early history, criminologists now and again have attempted to explain some of the mechanisms of justice, but this was mostly a philosophical project regarding the law. Critical theorists (e.g., Marxist theorists), for example, began to take on the justice system, in particular its relation to larger social structures and mechanisms. By and large, though, the core concern of criminology was crime and its causes.

The Influence of Criminal Justice

A somewhat radical change in this pattern occurred when the field of *criminal justice*, related to but distinguishable from criminology, was introduced as a separate area of study. As criminologists continued to study crime and its causes, scholars of criminal justice announced their intention to study the operations of the criminal justice system. Not merely a theoretical enterprise, the academic field of criminal justice sought to understand the problems and prospects of criminal justice, including an assessment of its effectiveness.

An assessment of effectiveness entailed necessarily a concern for how well the criminal justice system worked, which in turn implied the ability to give advice on how it should work and what might be done to increase its effectiveness. In other words, scholars of criminal justice began to enter the world of policy and practice.

The growth of academic criminal justice through the 1970s coincided with the upward spike in crime, the politicization of crime policy, and substantial growth in the size and impact of the criminal justice system. Beginning in the mid- to late 1960s and continuing through the early 1970s,

crime rates began to rise quite rapidly. Although today there is debate about just how much crime actually increased over the period, there is little doubt that the perception that crime was increasing rapidly led to elevated fear of crime and an increasing sense of urgency regarding the problem of crime. At about the same time, the foundations of the criminal justice system’s rehabilitative orientation were being questioned, and a new approach emphasizing crime control was offered. Over this period, crime policy became highly politicized. If deemed not “tough enough” on crime, politicians usually saw their political aspirations dashed. Legislatures enacted tougher crime policies, frequently with little to no debate. The new get-tough policies frequently produced injustices (and reproduced inequalities) in ways that criminologists found increasingly troubling. Moreover, criminologists argued that a number of these initiatives were not only theoretically unsound but also ultimately counterproductive.

Increasing concern about the justice of crime policy led to an unprecedented increase in the number of scholars and students whose careers were concerned with criminal justice. Since 1980, the number of doctoral programs offering PhD degrees in criminal justice has increased dramatically, and the number of PhD graduates has increased as well, and still the market for academics remained ahead of the growth curve, as entry-level criminal justice job openings outpaced the number of new PhDs entering the market. The influence of criminal justice on the field of criminology has been quite profound.

Criminology and Criminal Justice

For some individuals there is a powerful uneasiness between those who identify themselves with the traditional (sociological) roots of criminology and its search for understanding crime and those who associate themselves with criminal justice and the search for the right policies. In particular, concern has grown around criminology’s perceived attempt to establish itself as a distinct discipline, severing its ties with sociology and other more established fields of inquiry. Joachim Savelsberg and Robert Sampson (2002), for example, expressed concern that as criminology has tried to assert its intellectual independence (and establish itself as a separate discipline), it has lost much of its academic credibility. According to Savelsberg and Sampson, part of this lost credibility can be attributed to the field’s reliance on government funding and the concomitant reliance on state definitions and ideas. Savelsberg and Sampson argued that the study of criminology is at its best when attached to another discipline and led by intellectual tradition and ideas instead of by government priorities and dollars. James Austin (2003) similarly suggested that criminology’s irrelevance can be attributed to a lack of knowledge. Although he did not explicitly advocate a return to sociological roots, Austin argued that criminologists have little “good science” to offer policymakers, in

large part because of the decline of scientific methods, unbridled speculation, researcher bias, and the heavy hand of government funders in criminological research.

Other individuals see a perfect melding between criminology and criminal justice as fields of inquiry. The best illustration of this melding is the “what-works” movement and its academic sibling, evidence-based criminology. The what-works movement draws most of its momentum from the now-infamous “nothing works” proclamation made by Robert Martinson and his colleagues in a seminal article published in the mid-1970s (Miller, 1989). Martinson et al. subjected research findings in the area of correctional rehabilitation to *meta-analysis*, an analytical method used to summarize research findings and isolate the size of effects across accumulated research studies. They used a primitive meta-analytic technique and, on the basis of their findings, argued that there was little evidence that rehabilitative programming had any appreciable effect. Although Martinson et al. did not offer a vision for what might work in place of rehabilitation, the take-away message became that we had been too “soft” on crime, and the gap left by rehabilitation was quickly filled with a full complement of new get-tough approaches to the problem of crime. Partly in reaction to the influence of Martinson et al.’s “nothing works” article, more recent criminologists have sought to provide better evidence as to “what works,” offering prescriptions for each of the major subareas of criminal justice (crime prevention, policing, juvenile justice, and corrections, among others).

In the late 1990s, the U.S. Congress asked for a comprehensive evaluation of program effectiveness in preventing crime. Congress’s request led the National Institute of Justice to commission a study of what works in crime prevention. The study, conducted by Lawrence Sherman and colleagues (1999), involved a review of more than 500 program impact evaluations. The researchers concluded that, in terms of crime prevention, some programs appeared to be working, some clearly did not work, and others showed promise. There were a number of programs for which the jury remained out, because the impact evaluations reviewed were not sound enough to allow the researchers to draw valid conclusions. Sherman et al. ultimately recommended that the Department of Justice primarily fund program evaluations seeking to address what works, particularly in high-crime urban areas.

The what-works paradigm draws on an evidence-based criminological approach. Evidence-based criminology requires that high-quality evaluation research form the basis of policy or practice and is perhaps best exemplified by The Campbell Collaboration, a group of interdisciplinary social scientists who undertake systematic reviews of research regarding the effectiveness of various social policies and practices. The Campbell Collaboration’s systematic reviews are designed to help inform both policy and practice through pulling together and synthesizing research findings to advance our understanding of best practices.

Despite the growing popularity of evidence-based criminology and the what-works paradigm, debate remains over what should constitute “evidence” and how high the bar

should be set before the social science of criminology and criminal justice might be in a position to inform public policy. Some scholars believe the bar should be set very high and that only research that relies on true experimental methods (with random assignment to experimental and control groups) meets the bar. Truly experimental research is understandably hard to come by in a field where random assignment is at best difficult to achieve and, in some cases, not possible. Consider, for example, policy-driven research examining the effectiveness of a diversion program for serious offenders. Randomly assigning some offenders to this noncustodial program and others to prison would raise ethical concerns and present some rather complicated logistical challenges.

Other scholars think that research that has been subjected to the scrutiny of others in the field through the peer review process has the capacity to inform public policy. This broader view recognizes that there are limits to what we currently know and that there are limitations to the research that criminologists conduct but advocates for a more fluid approach in which research constantly informs the process. As knowledge grows and changes, so might policy.

Criminology, Criminal Justice, and Public Policy

Today, there is a debate within criminology regarding whether, and how much, criminology (and its younger sibling, criminal justice) should seek to influence crime policy. Some have embraced a proactive policy approach, while others remain quite notably opposed.

Arguments Against Participation

Individuals who are opposed to a policy approach in the field say that (a) criminal justice is inherently political and that this politicization should be a matter of concern, (b) “evidence” in the field of criminology and criminal justice is not only nuanced but also constantly changing and therefore too fluid to be of much use, and (c) there are honest academic disputes among respected social scientists and that these disputes should be taken seriously. We present each of these arguments in turn.

Criminal Justice Is Inherently Political

Criminal justice involves partisan interests, political pressure, and compromise in ways that some people say are incompatible with science. These opponents would argue that politics distorts scientific inquiry, especially when the results of science are politically unpopular. Take for example, the complicated relationship between crime and incarceration. For at least the past three decades, the war on crime (and the war on drugs and, more recently, the war on terror) have involved a get-tough orientation to addressing the problem of crime. Driven in part by increasing crime

rates and in part by political and practical expediency, current strategies for addressing the problem of crime have led to unprecedented growth in the size of prison populations. Incarceration has, in some respects, been advanced as the one-size-fits-all answer to the problem of crime. Social science evidence suggests, however, that incarceration is at best limited in its ability to prevent or control crime and in some important ways problematic for crime prevention. Yet criminological research highlighting the limited impact of prison expansion policies is politically unpopular, because politicians seeking to address the concerns of their constituents see few other politically viable options.

Similarly, when studies conducted by criminologists kept finding that boot camps featuring shock incarceration as an environmental intervention did not work, a chasm grew between the research community and the policy community. Opening new boot camps across the country remained a priority of the Clinton Administration throughout Clinton's tenure, even as study after study uncovered disappointing results. The main reaction of the policy community was to increase funding for studies of boot camps, possibly in the hopes that a new set of findings might someday emerge.

Criminological Evidence Is Nuanced and Ever Changing

There is a related problem of the nature of academic evidence itself. The evidence generated through social science research is almost never definitive and almost always nuanced, yet to make evidence palatable for the policy process seems to require watering it down and removing the crucial nuances of scientific "fact." There is a tendency for those nuances to get lost during the political process. Studies of the recidivism rate of people convicted of sexual crimes shows that the risk represented by this subgroup is complex, depending on personal background and type of offense. These nuances are typically forgotten in the policy-writing process, however, and widely varying types of sex crimes are treated as identical for purposes of legal action.

Moreover, criminological evidence is constantly changing, suggesting that the knowledge within the field is a lot more dynamic than policy about crime is able to be. At one time, for example, there was a strong consensus that poverty "caused" crime, but that view has changed markedly as new evidence on the causes of crime emerge.

Nobody should be surprised if the evidentiary foundation of the field is dynamic rather than static; the purpose of criminological scholarship, after all, is to produce new evidence. To build policy on "facts" that may well be contravened by new evidence is to erect crime policy on a bed of shifting sands.

Academic Disputes Among Criminologists Show Why Policy Positions Are Problematic

There are honest disputes among serious scientists about what really works and how well. The death penalty

offers a good example. Although there is a growing consensus around the utility of the death penalty—with most criminologists arguing that it either does not deter crime or deters no more than a lengthy prison sentence—some criminologists continue to argue that pursuing the death penalty is worthwhile. Recently, for example, a series of empirical papers written by economists suggesting that the death penalty reduces the rate of homicide have challenged the field's widely accepted consensus that it does not have that effect.

Serious academic disputes exist around all of the most controversial or contentious criminological debates (with gun control offering yet another example). Perhaps more surprising is that these serious academic debates also exist around questions that are more fundamental to the field. The "crime decline" experienced across the United States from the latter part of the 1990s represents the most sustained decline in crime rates in at least 50 years. Its cause has been the subject of much criminological thought, as some of the most respected criminologists in the field have advanced theories and offered evidence to support those theories. Some have argued that more aggressive policing and/or a change in the orientation of policing contributed to the crime decline. Others have argued that more strict control and regulation of guns have reduced crime (in particular, violent crime). Many of these expert opinions conflict with one another and such debates just highlight how little we actually know for sure about crime, its causes, and its prevention. As any student of criminology can tell you, there are easily as many theories of crime as there are types of crime.

Arguments in Favor of Participation

Individuals who favor greater involvement of social science in the justice policy process say that (a) policy should be based on the best available evidence, (b) avoiding involvement simply allows for false claims of evidence, (c) avoiding involvement allows gross injustices to continue, and (d) the work of criminology can influence agency practice without necessarily engaging directly in the legislative process. Again, we present each of these arguments in turn.

Policy Should Be Based on the Best Available Evidence

Policies should be based on the best available evidence, not on whatever political fancy rules the day. The only way to do that is to make the evidence available to policymakers. Thus, it falls to criminologists—and in particular, the professional organizations that represent them—to inform policymakers of the evidence. Precisely because the evidence is so often heavily nuanced, this must be done in a proactive and interactive way, not merely by publishing articles and letting the chips fall where they may. The professional associations must approach policymakers and

speak to them in ways that assist policymakers in interpreting the evidence and translating that evidence into policy. Only then can policy become a reflection of evidence.

Staying Out of Policy Debates Allows Charlatans and False Claims of Evidence to Shape Them Instead

Avoiding involvement in the policy process opens the door for charlatans to take control on false claims of evidence. Washington, D.C., is filled with advocacy groups that seek to marshal evidence to support their favored policies. Often, the organization of evidence is quite slanted toward the favored policy position, ignoring studies that do not support the already-determined positions being promoted. This leads to a potpourri of policy strategies, often taking opposing positions but all citing evidence as the foundation for their claims. The role of criminology in such a setting is to help sort out the evidence, provide critical reviews of what is known, and help policymakers see which claims are most well supported by what is known and (of equal importance) what is “bunk.”

Remaining Removed From Policy Debates Leaves Gross Injustices Unaffected

To stay out of the policy process is to allow gross injustice to continue to dominate a field and to turn a blind eye to stupidity in policies. Many justice policies are, it is argued, known to be harmful. For the criminological community to remain mute when policies are proposed (or enacted) that are known to either make the problem worse or to result in untenable consequences is to tacitly participate in the perpetuation of injustice. Juvenile transfer laws, which result in charging juveniles as adults, are an excellent example, because research shows they fail to deter juvenile crime while resulting in worse treatment of juveniles under adult laws. To fail to speak out is to leave this mistreatment of youngsters unchallenged. Speaking out against unjust policies, from an informed and scientific point of view, seems an essential requirement of an ethical criminological profession. We would be shocked if, for example, the American Medical Association allowed policies to go forward without comment if they were demonstrably bad for the nation’s health. Why are we not shocked that criminologists do the same with crime policy?

There Are Good Reasons for Influencing Agency Practice

There are many ways that criminologists (and their work) can influence *agency practice* without having to get enmeshed in the legislative process. Joan Petersilia’s Center for Evidence-Based Corrections, housed in the University of California at Irvine, has just that mission in the California penal system. The National Institute of Corrections promulgates an annual agenda of technical

assistance using some of the nation’s most well-established scholars as vehicles for improving the practice of criminal justice agencies. Many, if not most, academic criminal justice programs enjoy strong relationships with practicing criminal justice agencies, not only feeding them students but also helping them plan, implement, and evaluate new policies. To perform this kind of service is counted as a positive on the tenure and promotion requirements of many colleges and universities, and rightfully so.

Informing Public Policy

Thinking about criminology and policy today, we must begin by recognizing that the policymaking process is indeed a process, with a formal legislative course of action (bill writing, lobbying, testimony, etc.) and attendant side effects. We should also recognize that scientific opinion is actively sought in this process and that opinion will be located whether the field of criminology is comfortable with that fact or not.

Individual Participation

There are four ways that individual criminologists can take intentional action that is designed to influence policy: (1) thoroughly addressing policy implications of their research in their work, (2) working with policy-involved organizations, (3) directly inserting themselves in the policy-making process, and (4) engaging the media.

Addressing Policy Implications

Criminologists routinely seek to publish their research findings in traditional outlets (journals) and in doing so usually submit their work to the peer review process. At its best, this peer review process provides some level of assurance that the research used acceptable methods and that the findings are relatively sound. In other words, the purpose of the peer review process is to ensure that only research meeting established quality standards is published. When seeking publication in peer review publications, the focus is naturally on the research and the findings, and therefore authors are discouraged from straying too far from the facts. In other words, lengthy discussions about what the findings might mean for either policy or practice are considered polemic and are discouraged. One way in which criminologists might seek to influence policy would be through more directly addressing the policy implications of their work. Several journals have been established that explicitly focus on the policy relevance of criminological research. Although this represents a small step in the direction of informing public policy, our own experience in developing the journal *Criminology & Public Policy* suggests that if the field wishes to influence policy through its science, merely publishing the work of academic

researchers in accessible venues will not be enough. Neither will it be enough to simply offer the media concisely written summaries of research findings with the policy prescriptions emphasized. It would seem that criminologists need to do more.

Working With Policy-Involved Organizations

A second way in which individual criminologists might become involved in the world of policy would be through working directly with policy-involved organizations. Agencies and organizations frequently seek to engage in collaborations with academic researchers to either evaluate specific programs or to put together proposals for new initiatives. A number of criminologists have made a substantial impact on criminal justice policy primarily through their working relationships with organizations and agencies that are directly involved in the criminal justice process. Joan Petersilia, for example, is well-known for her work with the California Department of Corrections and, through that work, has influenced correctional policy in California and beyond. Similarly, George Kelling, who is most well-known for his contribution to the “broken windows” model for policing, has worked closely with police departments over the years. Kelling’s work has led to the widespread adoption of the broken-windows model, not only in policing but also in other areas of the system, such as courts and corrections. In other words, working directly with the individuals responsible for administering criminal justice can have a substantial impact on policy.

Direct Engaging in the Legislative Process

The most direct way for criminologists to engage in the policy arena is through offering expert opinion at various points in the legislative process. Legislative bills do not simply become law: They are lobbied for, introduced, sent to committee, debated, and ultimately voted on. Criminologists could exert influence at many stages during this process. This influence could range from signing a petition, to sending a letter or a paper to legislators, to advising those who are drafting legislation and offering expert testimony during legislative debate. By far the most common way that criminologists insert themselves into the legislative process is through expert testimony. There is no systematic way that people are vetted for this testimony, but some criminologists are called on repeatedly to offer the legislature their understanding of the criminological wisdom of certain policies.

Engaging the Media

Experts are not only sought out for direct participation in the legislative process through testifying during hearings, they also are sought out for indirect participation in the policy process through engaging in debates that take place in the media. The power of this indirect participation to exert

influence on the policy process should not be underestimated. Research suggests that the relationship among the media, politicians, and the public is a powerful one. In many ways, the media—driven primarily by ratings—reflect (and perhaps shape) public interests, priorities, and sentiment. With the advent of 24-hour news networks and the proliferation of Internet news sites, the supply of news outlets has grown dramatically. These news outlets often rely on “experts” to buttress their news stories. Research has demonstrated that the media will turn to “expert sources” to support their stories whether those sources are academic experts or not. Criminal justice officials, practitioners, and even laypeople serve as experts in the absence of academic researchers. Michael Welch and colleagues (Welch, Fenwick, & Roberts, 1998) reported that other sources to which the media might turn when criminologists are not available (e.g., practitioners and criminal justice officials) are typically more ideological in orientation. Practitioners and others tend to rely on anecdotal evidence (as opposed to research evidence) and tend to advocate for more “hard” approaches to the problem of crime. Criminologist Greg Barak (2007) argued that criminologists ought to engage more deliberately in “newsmaking criminology.” Barak argued that, by engaging the media, criminologists can help set and shape the crime policy agenda.

Despite the opportunities to engage in newsmaking criminology, relatively few criminologists engage the media with any frequency. There are a handful of criminologists (e.g., James Alan Fox and Larry Kobilinsky) who routinely make themselves available to local and national media outlets. Most others engage the media on more of an ad hoc basis, typically following an individual request from a local news agency.

There are clearly some downsides to engaging the media. The media rely heavily on overly simplistic explanations for complex phenomena. In an age of sound bites and easily digestible news, much of the story—and almost all of the nuances—gets lost. Most criminologists who have worked with the media have tales to tell of misquotes or selective use of material that distort meaning.

Organizational Participation

It is one thing for criminologists, acting as private citizens, to insert themselves into the policy process. It is quite another for formal associations, such as the American Society of Criminology (ASC) or the Academy of Criminal Justice Sciences (ACJS), to take formal organizational action in this arena. The main way these organizations have, to date, been active in the policy process is by a very limited role, such as supporting the work of the specialist scientific group Consortium of Social Science Associations. However, that is now changing. For about 5 years, the ACJS has had a public policy section that has a presence in Washington, D.C., and writes a newsletter about what is happening in the politics of crime. Also, the ASC recently

contracted with a firm in DC to strengthen its voice on Capitol Hill.

Levels of organizational participation in the policy process, in order of “comfort” for the field, might include the following:

1. Advocating for the best possible quality of crime and justice statistics
2. Advocating for scientific peer review process for funding crime and justice research
3. Advocating for large crime research budgets
4. Commissioning the writing of white papers that summarize what is known about a topic
5. Supporting expert testimony before legislative bodies
6. Vetting experts to testify about specific legislation
7. Taking formal organizational positions in crime and justice matters

These are all strategies that are variously taken by one or another of other professional societies (the American Medical Association, American Bar Association, American Sociological Association), and so there is precedent for each of these kinds of participation by criminology. We now briefly review each type of participation.

Advocating for Quality Criminal Justice Data

Quite a bit of the work of criminologists draws on official data collected by various federal agencies. The Federal Bureau of Investigation collects and compiles crime data through the Uniform Crime Reports (UCR) and the National Incident Based Reporting System. The Bureau of Justice Statistics, alone and in collaboration with the Bureau of the Census, also collects criminal justice data, including, among many others, the National Crime Victimization Survey, the National Corrections Reporting Program, and the National Judicial Reporting Program. Similarly, a number of other federal agencies undertake substantial data collection efforts that address criminal justice issues. These data are used by criminologists as they conduct their research. As is always the case, the quality of the data will, in large part, dictate the quality of the research and the reliability of the findings. Criminologists therefore have a vested interest in ensuring the quality and integrity of these data. Just as important, these data are also sometimes used by the media and unscrupulous criminologists in ways that are seen as problematic by many in the field. Some of the ways in which UCR data have been used—for instance, to rank the nation’s safest or most dangerous cities—are particularly troubling because they rely on overly simplistic rankings of the raw data. Individually or collectively, criminologists might advocate for the collection of quality criminal justice data and for appropriate and responsible use of official data.

Advocating for Scientific Peer Review Processes

Just as some of the data used by criminologists as they conduct their research is generated by government agencies,

some of the research in the area of crime and justice is funded by those very same agencies. The National Institute of Justice is one of the major funding sources for academic criminological research. The National Institutes of Health; its subsidiary, the National Institute on Drug Abuse; the Office of Juvenile Justice and Delinquency Prevention; and the National Science Foundation also fund research in the areas of criminology and criminal justice. Although the amount of funding set aside for research might vary across presidential administrations, the need for quality controls in the selection of projects identified for funding should not. To that end, academic criminologists seeking to influence public policy sometimes actively involve themselves in the funding selection processes by advocating for peer review processes and, in some instances, serving as peer reviewers.

Advocating for Research Budgets

Criminologists and criminological organizations have at times advocated on behalf of agencies and bureaus involved in the data collection and research funding enterprises. When local, state, and federal budgets are tight (or in crisis), the tendency has been to reduce or eliminate research funding. Some people would argue this strategy is shortsighted because criminological research has the capacity to address fundamental questions of public policy. The Consortium of Social Science Associations serves as a national umbrella organization that promotes social science research. Criminology is quite well represented in that lobbying group.

Commissioning White Papers

Professional criminological organizations might also engage in the commissioning of white papers that summarize what we collectively know about an issue based on the accumulated evidence. This is particularly important because one of the major barriers to effective participation in the policy-making process has been the issue of accessibility. Research findings in the field of criminology typically appear in academic journals and books written for academic audiences. These journals and books are frequently loaded with relatively advanced statistical methods, complicated descriptions of the findings, and no small amount of academic jargon. In other words, the findings are not particularly accessible to a general audience or to policymakers. Moreover, the findings often represent a small piece of a much larger puzzle. Findings from one study typically build on findings from previously published work. Experts in the field may be familiar with the accumulated body of evidence, whereas those in a general audience would typically not be. White papers can draw on and more concisely summarize the collection of research findings in a particular area.

An annual publication, *Crime and Justice: A Review of Research*, published by the University of Chicago Press and edited by Michael Tonry, does this for research findings

across a number of areas. The National Academy of Sciences also has commissioned works that synthesize and summarize the state of knowledge within a particular area (perhaps most notably, deterrence and gun control). White papers commissioned by professional associations could be drafted in response to pressing issues of public policy. These reports could adeptly synthesize what criminology as a field has to offer in the form of contributions to our understanding of the issue. The white papers fall short of offering official positions and instead provide information relevant to and necessary for making informed decisions around policy issues.

The ASC has experimented with the white-paper process, but not very successfully. After two white papers were written on incarceration policy, the ASC's executive board decided to end the process because it was deemed not to fit very well with the way the organization works. White papers were seen as too politically controversial to be sustainable by the organization, and no easy process for vetting the papers throughout the whole organization was available.

Supporting Expert Testimony Before Legislative Bodies

Another way professional organizations could become more directly involved in the policy arena would be through supporting expert testimony before legislative bodies. Most bills that are introduced in legislatures are subject to some debate before they come to a vote. All sorts of legislation related to crime and justice policy makes its way through this process without any input from criminologists or criminal justice experts. Professional organizations might provide funding or simply encourage their memberships to more actively involve themselves in the legislative process.

Vetting Experts to Testify About Specific Legislation

Professional organizations—and in particular their executive boards—might vet experts to testify about specific legislation. For example, if legislation proposing stricter limits on access to guns were up for discussion, professional organizations could solicit the participation of known experts in the field, perhaps carefully selecting experts representing a variety of viewpoints. The criminological organization could establish a stable of people who have been identified as having unassailable expertise in given areas and then promote their testimony on legislative matters as they arise.

Taking Formal Organizational Positions

Although some professional organizations (e.g., the American Bar Association) quite routinely announce official organizational positions on issues of importance to their field, the two largest professional criminological

associations—the ASC and the ACJS—have been more reluctant to take formal (e.g., official) positions on matters of criminal justice policy. To date, the ASC has officially taken official policy positions on just two issues: (1) the death penalty and (2) the irresponsible use of crime data. In 1989, the ASC issued its first official policy position proclaiming opposition to the death penalty:

Be it resolved that because social science research has demonstrated the death penalty to be racist in application and social science research has found no consistent evidence of crime deterrence through execution, The American Society of Criminology publicly condemns this form of punishment, and urges its members to use their professional skills in legislatures and courts to seek a speedy abolition of this form of punishment. (American Society of Criminology, n.d.)

Although the ASC's official position on the death penalty reflects the wider membership's general opposition to capital punishment, not all members support that view; neither would all members agree with the official position taken. In part because of concern about announcing official positions in a field in which there are notable differences of opinion, the ASC's death penalty position stood as the sole policy position for nearly 20 years until, in 2007, the ASC board voted to announce a second official policy position, regarding the irresponsible use of crime data. Amid growing concern that official crime data were being misused and misrepresented (particularly in the media), in November 2007, the executive board of the ASC took an official policy position with regard to the use of UCR data:

Be it resolved, that the Executive Board of the American Society of Criminology opposes the use of Uniform Crime Reports data to rank American cities as “dangerous” or “safe” without proper consideration of the limitations of these data. Such rankings are invalid, damaging, and irresponsible. They fail to account for the many conditions affecting crime rates, the mis-measurement of crime, large community differences in crime within cities, and the factors affecting individuals' crime risk. City crime rankings make no one safer, but they can harm the cities they tarnish and divert attention from the individual and community characteristics that elevate crime in all cities. The Executive Board of the American Society of Criminology urges media outlets to subject city crime rankings to scientifically sound evaluation and will make crime experts available to assist in this vital public responsibility. (American Society of Criminology, n.d.)

In addition to announcing official policy positions of the organization, the ASC has also convened a National Policy Committee. As mentioned previously, earlier iterations of the ASC's National Policy Committee have issued two policy papers (i.e., white papers). Each of these white papers makes clear through a disclaimer that the papers express the views of their authors and do not represent official policy positions of the organization (although clearly the policy paper on the death penalty supports the ASC's previously announced official position on the death penalty).

Conclusion

The purpose of this chapter was to review the position of criminology and criminal justice relative to the world of public policy. Despite an obvious relevance, the field of criminology has historically exhibited a reluctance to engage in questions of public policy in any systematic or concerted manner. Although there are some notable individual exceptions, as a group criminologists have been reticent to participate in the process. Criminological associations have expressed even more reservations regarding such participation.

We should be clear that the state of criminology as a field related to public policy is changing. Where it is headed we cannot say, but there is almost a certainty that the extremely limited participation of the field that has characterized its history is ending. Debates today are less about *whether* to participate and more about how *best* to participate in the policy arena.

PART II

CORRELATES OF CRIME AND VICTIMIZATION

4

AGE AND CRIME

LEANA A. BOUFFARD

Washington State University

The curvilinear relationship between age and crime is one of the most consistent findings in criminology, and it has been referred to as a “resilient empirical regularity” (Brame & Piquero, 2003, p. 107) and “one of the brute facts of criminology” (Hirschi & Gottfredson, 1983, p. 552). Social statisticians as early as Quetelet in the 1800s (Steffensmeier, Allan, Harer, & Streifel, 1989) identified a strong relationship between age and crime that has come to be known as the *age–crime curve*. The general form of the relationship between age and crime is not much debated. In aggregate studies, the age–crime curve is unimodal, with official crime rates rising in adolescence to a peak in the late teenage years and then declining rapidly through adulthood. It is also apparent that the age–crime curve peaks somewhat later for violent crimes as compared with property crimes. Although much research examining the age–crime relationship has relied on official data and age-specific arrest rates (Marvell & Moody, 1991), Moffitt (1993) noted that the general curvilinear pattern also holds true more generally for conduct disorder, antisocial behavior, and childhood aggression. Farrington (1986) and Hirschi and Gottfredson (1983) have commented that although scholars agree on the general form of the age–crime curve, there is less agreement on its meaning and implications.

Hirschi and Gottfredson’s “Age and the Explanation of Crime”

Many scholars have pointed to Hirschi and Gottfredson’s (1983) seminal article, “Age and the Explanation of Crime,” as the beginning of serious debate surrounding the relationship between age and crime. This debate centers around a number of factors, both methodological and theoretical. Specifically, Hirschi and Gottfredson set forth a number of basic perspectives on the relationship between age and crime. First, and perhaps most important, these authors argued that the age–crime curve is invariant across a wide variety of social and cultural factors, including time, place, individuals, and types of crime. Although they recognized that there may be differences in levels of offending among groups (e.g., males and females), they dismissed this variation in favor of the conclusion that the general form of the curve is the same. This invariance argument has profound implications for methodological, theoretical, and practical considerations in criminology and has provoked intense debate among criminologists that are visited in more detail later in this chapter.

Hirschi and Gottfredson (1983) also addressed theoretical attempts to contend with the age–crime curve, arguing that theories should not be obligated to try to explain this

relationship and should not be rejected solely because of their inability to do so. The authors further contended that no existing criminological theories are capable of explaining the age–crime curve. In the absence of strong theoretical explanations, Hirschi and Gottfredson suggested that age has a direct effect on crime and on other social factors proposed to explain crime. An apparent relationship between marriage and reduced offending is spurious, because age causes both; in other words, this relationship appears only because individuals get married and begin to age out of crime at the same time. Finally, Hirschi and Gottfredson argued that conceptualizing the age–crime relationship in terms of a criminal career is unnecessary and potentially misleading, especially because the causes of crime are the same at all ages throughout life.

The arguments Hirschi and Gottfredson (1983) put forth in their article have spurred a great deal of debate in the field and have far-reaching implications for criminological research, theory, and policy. Tittle and Grasmick (1998), for example, argued that Hirschi and Gottfredson's perspective presents a major challenge to many current directions in criminology, including the criminal careers perspective, longitudinal research, developmental theories, and social theories in general. Subsequent sections of this chapter explore the methodological, theoretical, and policy implications of these various arguments about the age–crime curve.

Methodological Implications of the Invariance Argument

Steffensmeier and colleagues (Steffensmeier, Allan, Harer, & Streifel, 1989) noted disagreement about the strength and consistency of the relationship between age and crime. One of the main methodological points of argument stems from Hirschi and Gottfredson's (1983) assertion that the age–crime curve is invariant across time, place, individual characteristics, offense type, and so on. Many criminologists have addressed this argument and contend that the claim of invariance is overstated. In summarizing the debate, Tittle and Grasmick (1998) found evidence of invariance only when considering the general mathematical form of the curve; in other words, the aggregate age–crime curve looks similar across different places, times, types of individuals, and offense types. All curves share the same general unimodal pattern of rising rates to a peak in late adolescence and declining rates through adulthood. However, Tittle and Grasmick (1998) commented that the claims of parametric and individualistic invariance have been conclusively rejected.

In terms of parametric invariance, studies examining the specific properties of the age–crime curve (i.e., median,

mean, skewness, and kurtosis) have found variations (see Farrington, 1986, and Tittle & Grasmick, 1998). For example, using both the Uniform Crime Reports and self-report data, Steffensmeier and colleagues (1989) found that whereas the general shape of the aggregate curves are similar, specific parameters of the curve do vary. They noted in particular that, over time, the peak of the age–crime curve has shifted to younger ages and the curve has become steeper. In his study of the specific components of the curve, Farrington (1986) also concluded that the age–crime curve is not invariant. Although Gottfredson and Hirschi (1986) dismissed these variations as unimportant, others find them to be substantively interesting and worth attention (Blumstein, Cohen, & Farrington, 1988).

The claim of invariance has also been rejected when the age–crime curve is considered at the individual level. Tittle and Grasmick (1998) noted many individual deviations from the modal age–crime curve. Blumstein and colleagues (1988) argued that because the aggregate age–crime curve is capturing prevalence (e.g., the proportion of the population of a given age that engages in crime), it only appears to be invariant. When one looks at the relationship between age and crime at the individual level, however, one can see a great deal of variation. Farrington (1986) also cited individual variation in offending trajectories, which have been replicated in more recent research (see Nagin & Land, 1993).

This highlights an important methodological debate in terms of whether the relationship between age and crime is due to prevalence (i.e., participation rates) or incidence (i.e., individual patterns of the frequency of offending). Differences in prevalence or participation rates of offending imply that the general shape of the age–crime curve appears because involvement in offending varies by age group. In other words, a larger proportion of the adolescent population participates in offending, while the proportion of the population involved in offending declines for older age groups. A consideration of incidence or frequency of offending, on the other hand, suggests that the age–crime curve is an aggregate representation of individual differences in the number of crimes committed at various ages. In other words, individuals commit a larger number of offenses during their adolescent years and reduce the frequency of their offending as they age. It is now generally agreed that the relationship apparent in the aggregate age–crime curve is due to prevalence (Farrington, 1986; Moffitt, 1993). Beginning with the work of Nagin and Land (1993), studies have continued to demonstrate variation in trajectories of the frequency of offending. Hirschi and Gottfredson (1983) also agreed, and they further argued that differences in prevalence (i.e., distinguishing accurately between offenders and nonoffenders) are the most important consideration in criminology.

Age, Crime, and Criminal Careers

Other methodological debates surrounding the relationship between age and crime largely stem from the issue of the invariance of the age–crime curve. The claim of individualistic invariance has been rejected, and some researchers, recognizing that there are individual variations in the age–crime relationship, have considered offending in the context of a criminal career. Blumstein et al. (1988) referred to the *criminal career* as “the longitudinal sequence of offenses committed by an offender who has a detectable rate of offending during some period” (p. 2). The criminal careers perspective looks at the relationship between age and crime at the individual level and addresses such components of a career as onset, persistence, and desistance. *Onset* refers to the initiation of criminal behavior, and some researchers have focused on age of onset as an important element of the criminal career. In particular, research has examined whether individuals who initiate their offending early in life are more likely to become long-term or high-rate offenders. *Persistence* refers to the continuation or duration of an offending career, and *desistance* refers to the termination of that career. Although Blumstein et al. argued that there is no reason to expect any particular pattern or tendency within criminal careers, they suggested that the inquiry as to the presence of certain patterns (e.g., escalation in seriousness, specialization in particular types of crime, etc.) is open to empirical investigation.

The criminal careers perspective does not present any particular theoretical model; instead, it is a methodological and empirical strategy that separately considers participation in offending from the frequency of offending among active offenders and allows for the possibility that various theoretical perspectives may be important in explaining different components of the criminal career. Gottfredson and Hirschi (1986), on the other hand, contended that the appropriate comparison for criminology is between offenders and nonoffenders (i.e., prevalence or participation) and that theories that are capable of distinguishing these two groups are adequate without needing to explain different components of a career. For Gottfredson and Hirschi, questions of the incidence or frequency of offending are irrelevant to the understanding of criminal behavior, and the causes of crime are the same regardless of age or criminal career component.

Longitudinal Research in Criminology

The age–crime curve and the criminal career perspective both imply long-term processes at work. For a variety of reasons, longitudinal studies, which involve repeated measurement over time, have emerged as preferable to cross-sectional studies (i.e., measurement at one point in time) in the study of criminal careers. Blumstein and colleagues (1988) argued that understanding dynamic patterns of offending, whether one is looking for variation or stability, virtually requires longitudinal data,

and they pointed to the inadequacies of cross-sectional data in studying criminal careers. Steffensmeier et al. (1989) likewise argued that there are many social factors that vary by age and that may provide an explanation for the shape of the age–crime curve. Greenberg (1985) pointed out that the impact of dynamic factors will be underestimated in cross-sectional analyses depending on the stability or instability of the variable over time. The distinction between longitudinal and cross-sectional data may be most important when causal ordering is unclear. For example, whereas social control theories propose that weakened social bonds will lead to criminal behavior, it is also plausible that involvement in offending may weaken social bonds (Greenberg, 1985). By measuring social factors and criminal behavior at various points in time, longitudinal studies are better able to ensure the appropriate temporal ordering necessary to demonstrate causation instead of just correlation.

Another important consideration in choosing between cross-sectional and longitudinal research was raised by Farrington (1986), who argued that cross-sectional research easily confuses period, cohort, and age effects. *Period effects* refers to the impact of living in a particular historical period. Regardless of age, individuals who live through particular periods (e.g., World War II) may experience the same events or social conditions. *Cohort effects* may be more easily confused with age effects in that individuals in the same cohort (e.g., born in the same year) may be exposed to similar life experiences (e.g., the Baby Boomer generation). In contrast, the term *aging effects* refers to those social conditions that may vary by age (e.g., maturational reform, changes in peer networks or social bonds, etc.) and would affect individuals regardless of cohort or period. Farrington argued for the necessity of using multicohort longitudinal studies to truly distinguish these period, cohort, and age effects.

Gottfredson and Hirschi (1986, 1987), however, have taken issue with many of these arguments. Hirschi and Gottfredson (1983) argued that if the age–crime curve is the same for everyone, then no special techniques are necessary to understand this relationship. They argued that good cross-sectional studies (e.g., true experiments) are capable of answering the same questions as longitudinal designs, especially considering that the timing of crime and social events is not ambiguous. Because temporal ordering should not be a major problem when studying criminal behavior, according to this perspective one major argument in favor of longitudinal designs is rejected. They also discounted the need to disentangle age, period, and cohort effects, because “crime cannot cause age, period, or cohort” (Gottfredson & Hirschi, 1987, p. 588), and they argued that the attention paid to these issues has distracted criminology from more substantive, policy-relevant concerns.

Gottfredson and Hirschi (1987) also contended that the correlates of crime uncovered by longitudinal research are the same as those reported by cross-sectional research, concluding that longitudinal studies have merely confirmed

results from cross-sectional studies. They cautioned that longitudinal studies are far more expensive, inefficient, and time consuming than cross-sectional studies, providing no added value to the study of crime. Other researchers have pointed to additional difficulties of longitudinal research, including the possible confusion of testing and maturation or aging effects and the high levels of attrition (i.e., dropping out) of high-rate chronic offenders from longitudinal studies over time (Brame & Piquero, 2003).

This debate is far from settled. Gottfredson and Hirschi (1987) contended that the invariance of the age–crime curve means that nothing of value has been learned from longitudinal studies and that it is more important to distinguish offenders from nonoffenders, regardless of age. On the other hand, researchers who are interested in the incidence of offending (i.e., frequency) and criminal careers argue that the curve varies a great deal at the individual level and requires longitudinal data to truly understand the patterns. Sampson and Laub (1995), for example, suggested that although differences between offenders are important, differences within individuals over time are just as important to understand. Scholars, especially those in the criminal careers or developmental/life course traditions, are increasingly turning to individual-level, longitudinal designs (Brame & Piquero, 2003). This research continues to find evidence of varying criminal career patterns and to explore whether different social factors may account for these different patterns (Nagin & Land, 1993; Steffensmeier et al., 1989).

Theoretical Implications of the Age–Crime Relationship

Debate over the age–crime curve also has significant implications for criminological theory. Hirschi and Gottfredson (1983) claimed that the age–crime curve is invariant, that the causes of crime are the same at all ages, and that no existing social theory is capable of explaining the curve. Traditional criminological theories, such as differential association and social control, have tended to focus on explaining crime during the adolescent period, which represents the peak of the age–crime curve. Although this is to be expected, given that the bulk of delinquent and criminal activity occurs during these ages, Greenberg (1985) argued that crime does not just level off following the transition to adulthood; instead, it consistently declines, which suggests the need for theoretical attention to the entire life span and to the decline and desistance from offending in addition to onset.

Hirschi and Gottfredson (1983) noted that traditional theories have often been judged by their ability to explain the patterns apparent in the age–crime curve. For example, theories are criticized as being able to explain the onset of criminality, leading to the peak of offending, but not desistance. The failure to explain all aspects of the age–crime curve is often taken as a fatal flaw for theories. Hirschi and

Gottfredson argued, however, that a theory that adequately distinguishes offenders from nonoffenders at a particular age (e.g., adolescence) may not necessarily account for the aging-out effect. Because aging out and desistance from crime occur consistently for all groups, the failure to explain desistance should not be used to discount a theory, especially considering that no existing theory, in their opinion, is capable of providing an adequate explanation.

Hirschi and Gottfredson (1983) also argued that, in the absence of a sufficient theoretical explanation, the remaining conclusion is that age has a direct effect on crime independent of other social factors and incapable of being explained by any existing social theories. This would seem to imply some sort of biological explanation, and they referred to a process of *maturational reform*, which occurs pervasively for all offenders, as an explanation of desistance. Farrington (1986) also suggested that maturational reform reflects some biological forces, noting age-related variation in physical strength and skills. Again, according to Gottfredson and Hirschi (1986), because the age–crime curve is invariant, and because aging out of crime occurs similarly for everyone, attempts to explain these patterns with social forces, which are assumed to vary, is futile. These authors ultimately concluded that the correlation between various social factors and crime is spurious, calling into question all existing criminological theories.

The Age–Crime Relationship in Traditional Criminological Theory

Despite the critique leveled by Hirschi and Gottfredson (1983), the major theoretical traditions in criminology (i.e., strain, social control, and social learning theories) have all been used to provide explanations for variation in criminal behavior over the life span. For example, *strain theory* argues that adolescents and young adults experience more status frustration and strain, which eases with entry into adulthood and legitimate employment. The relative deprivation experienced by youth declines with entry into the legitimate adult labor market (Greenberg, 1985). Theorists have also incorporated some elements of strain theory when considering Easterlin's (1978) perspective on relative cohort size. Easterlin argued that larger cohorts (e.g., the Baby Boomers) face certain disadvantages, such as competition for scarce resources, that result in higher levels of economic deprivation for that cohort. Although Easterlin highlighted the negative economic conditions consistent with a strain perspective, he also suggested that large cohorts may overwhelm social institutions, subjecting cohort members to additional criminogenic social conditions, such as reduced supervision, weakened socialization, and lower levels of social control. These conditions prove to be most detrimental for adolescents and young adults and may account for increasing crime rates when these large cohorts enter the most crime-prone years (i.e., late adolescence and early adulthood).

As Easterlin (1978) and Greenberg (1985) suggested, social control theory may also provide an argument for the changing of crime rates by age. Sampson and Laub (1995) pointed out that the impact of both formal and informal social controls varies by age. This theory argues that social bonds are weakened during adolescence, freeing an individual to violate social norms. Thus, adolescence represents a time when attachments to conventional others, especially parents, and commitment to conventional institutions are reduced. Social bonds may be re-formed in adulthood as individuals accumulate conventional ties to jobs and begin to build their own families through marriage and parenthood. In addition, the consequences of crime become more serious with age and function as more of a control on behavior as individuals amass a greater stake in conformity (Steffensmeier et al., 1989).

Differential association would anticipate that increasing involvement in crime during the adolescent years is due to variation in experiences with delinquent peers (Warr, 1993). In support of this perspective, Warr (1993) used data from the National Youth Survey to demonstrate age-related changes in exposure to delinquent peers, including the percentage of friends who are delinquent, time spent with peers, and the self-reported importance of peers, that correspond to the age-crime curve. During later periods of adolescence individuals in the National Youth Survey reported a larger number of delinquent friends, more time spent with those friends, and more importance of peers in their lives. In multivariate models, the relationship between age and crime was attenuated when peer variables were included. Thus, Warr's research suggests that the age-crime relationship may be at least partially explained by changes in peer associations.

Stolzenberg and D'Alessio (2008) more recently examined the implications of peer association in a different way, addressing whether changes in co-offending account for age-related variations in criminal involvement. Researchers have consistently noted that criminal behavior during adolescence is largely a group phenomenon. This pattern of co-offending may explain the increasing prevalence rates during adolescence that are apparent in the aggregate age-crime curve. Stolzenberg and D'Alessio put forth the following argument:

[The] greater prevalence of co-offending among juveniles, engendered to a large extent from the influence of criminally inclined peers, in turn explains why crime levels peak during adolescence and then begin to decline in early adulthood following graduation from high school. (p. 69)

If this perspective is true, the age-crime relationship should be most apparent when one is considering crimes involving co-offending, but it should disappear when co-offending is taken into account. In other words, the age-crime curve for solo offending should be flat, whereas the curve for co-offending should demonstrate the typical

curvilinear pattern. Using National Incident Based Reporting System data, however, Stolzenberg and D'Alessio (2008) found two interesting results. First, contrary to much of the discussion surrounding adolescent offending, co-offenses are not the most common pattern; instead, solo offending is more common for all age groups, including juveniles. Also, the age-crime curve emerges for both solo and co-offending, suggesting that accounting for co-offending does not attenuate the typical age-crime relationship. Thus, patterns of co-offending do not appear to account for the age-crime curve.

Marvell and Moody (1991) argued that although there is no shortage of speculation about the causes of the age-crime curve, there is little empirical support for any of these explanations, concluding that there is no firm theoretical foundation for the age-crime curve. Tittle and Grasmick (1998) examined a variety of age-varying criminogenic factors but found that including these factors did not seem to account for the age-crime relationship. They reported an inability to discount Hirschi and Gottfredson's (1983) theoretical arguments and concluded that it is not easy to explain away the age-crime curve.

Propensity Versus Developmental Theories

More recent criminological theories have attempted to explain the curve itself as well as to understand changes in levels of crime over the course of the age-crime curve. Two strategies of accounting for variation across the life course are apparent in criminological theory: (a) propensity theories and (b) developmental or life course theories. *Propensity theories* point to a single underlying stable trait that causes crime at all ages. The most well-known and most frequently tested propensity theory in criminology is Gottfredson and Hirschi's (1990) general theory of crime, which suggests that crime and other risky behaviors at all ages are the result of an individual's low level of self-control. Using a theoretically stable trait to account for obvious age-related variation in criminal offending patterns may seem counterintuitive. Gottfredson and Hirschi contended that low self-control produces criminal behavior in the presence of criminogenic opportunities. Thus, opportunities for crime may vary across the life course even though levels of self-control are relatively stable. Hirschi and Gottfredson (1995) suggested that variation in the opportunity for crime by age accounts for a great deal of the variation in actual criminal activity observed.

In concert with their earlier assertion that the relationship between age-varying social factors and offending is spurious because of age (Hirschi & Gottfredson, 1983), propensity theory argues that any relationship between social factors (e.g., deviant peer associations and weak social bonds) and offending is spurious because of self-control. In other words, deviant peer associations and weakened social bonds are related to offending because they are all caused by the underlying factor of self-control.

Individuals with low levels of self-control are also more likely to associate with deviant peers and have difficulty forging and maintaining the conventional connections that foster strong social bonds. Thus, they continue to argue that criminological theories attributing changes in offending over time to changes in social factors are inadequate.

In contrast to propensity theories, *developmental or life course theories of offending* point to age-related variations in criminogenic factors to explicitly account for the age-crime relationship. Both developmental and life course theories look to the full life course in their explanations of offending. Moffitt's (1993) developmental theory, for example, starts with the conclusion, based on empirical research, that the age-crime curve represents differences in prevalence by age, with a larger proportion of the adolescent population engaging in delinquent or criminal activity. She also argued that the aggregate age-crime curve masks group differences in the relationship between age and crime. In other words, she noted that individual variation in the frequency of offending by age is hidden within the aggregate age-crime curve.

Moffitt (1993) proposed a typological perspective that identifies two separate groups of offenders, each with a different age-crime curve. Thus, the aggregate age-crime curve is a mix of a small group of long-term offenders (referred to as the *life-course-persistent offenders*), which has a relatively flat and stable age-crime curve, and a larger group of individuals with a short-term period of delinquent involvement occurring during adolescence (referred to as *adolescent-limited offenders*), which demonstrates the typical age-crime curve with a large peak during late adolescence. With two different offending patterns, these two groups require different etiological explanations. According to Moffitt, life-course-persistent offenders become involved in criminal behavior early in life and persist in their criminal activity because of the combination of neuropsychological deficits, inadequate parenting, and cumulative disadvantage associated with the negative consequences of early criminal involvement. Adolescent-limited offenders, on the other hand, engage in offending for a relatively short duration. Entry into offending is explained by a maturity gap, in which youth may be biologically mature but remain dependent on and under the control of their families. Minor offending occurs in an attempt to gain some independence and as a result of the imitation of antisocial models. Desistance in this group occurs in early adulthood as social bonds increase and the consequences of criminal activity become more punitive.

Life course theories of offending similarly point to long-term patterns of offending and social forces that operate over the full life course. Sampson and Laub's (1993) *age-graded theory of social control* highlights the processes of both continuity and change in behavior over the life course, looking at both differences between individuals and differences within individuals over time. Entry into delinquent behavior is accounted for by a variety of

social factors, including weak social bonds to family and school in childhood and adolescence. Desistance from delinquency occurs with the accumulation of social bonds, namely, strong marriages, stable employment, and other stabilizing influences, in the transition to adulthood. Persistence (i.e., continuity), on the other hand, occurs as a result of the cumulative disadvantage of early criminal involvement. Sampson and Laub (1995) contended that criminal behavior further attenuates already-weakened social bonds by limiting opportunities within conventional society. Some scholars have argued that the focus on social bonding is too narrow and that many life events may function to alter peer association more in line with a learning perspective instead of a social control perspective (Stolzenberg & D'Alessio, 2008). Sampson and Laub (1995) contended that this does not directly contradict their theory, and the most recent version of the theory (Laub & Sampson, 2003) has expanded to accommodate social bonding, peer, and routine activity influences that change over the life course. For example, marriage may strengthen social bonds as well as attenuate preexisting deviant peer associations and restructure routine activities and criminal opportunities. These life events, then, account for the peak of offending during late adolescence and the dramatic decline in offending that occurs shortly after the transition to adulthood.

Variation in the Causes of Crime by Age

One question remaining from traditional and life course/developmental theories is whether the causes of crime are the same regardless of age. As might be expected, Hirschi and Gottfredson (1983; Gottfredson & Hirschi, 1990) have argued that the causes of crime are the same at all ages; in other words, social factors do not interact with age to produce criminal behavior. Other theorists suggest that the causes of offending may vary by age. For example, Moffitt (1993) pointed to a variety of theoretical factors that may influence offending at different ages, including early neuropsychological deficits and parenting influences, negative peer associations in adolescence, and social control mechanisms in later adolescence and early adulthood. Tittle and Grasmick (1998) examined the interaction thesis and found no evidence that age interacts with criminogenic forces to produce criminal behavior. Again, they had difficulty discounting Hirschi and Gottfredson's (1983) assertions; however, this issue remains open for debate and empirical investigation.

Practical and Policy Implications of the Age-Crime Relationship

The debate surrounding the relationship between age and crime has also highlighted some practical and policy implications. Existing criminal justice policies have often

been assessed in relation to the implications of the age-crime curve. For example, strategies such as the *three-strikes law* (according to which courts are required to hand down a mandatory incarceration sentence to offenders who have been convicted of felonies three or more times) have been criticized in that, by the time the penalty for a third strike is implemented, the offender is likely at the end of his or her criminal career and would age out of criminal involvement regardless of the severity of the penalty. Other issues arise with regard to the appropriate crime reduction strategies implied by the age-crime curve and forecasting future trends in crime rates.

Targeting Participation Versus Frequency

The distinction between participation and frequency highlighted in the criminal careers debate proves to be an important consideration for crime policy. Hirschi and Gottfredson (1986) argued that programs targeted at reducing participation rates (i.e., reducing the proportion of the population that is engaging in criminal behavior) will have the largest effect on crime rates. They advocated for early intervention programs in particular. Farrington (1986) likewise suggested that, because the aggregate age-crime curve represents differences in participation, the best strategy to reduce crime is to prevent its onset by investing in early intervention programs. Blumstein and colleagues (1988), however, suggested that this is only one approach to decreasing crime. A second approach would be to reduce the frequency of offending among active offenders, which would involve more criminal justice strategy. These authors argued that there is a small group of offenders with a high frequency of offending and a relatively flat, stable age-crime curve (e.g., “chronic offenders” or “career criminals,” recognized as early as 1972 by Wolfgang, Figlio, & Sellin). A strategy such as selective incapacitation, which is targeted at reducing the frequency of offending among these chronic offenders, might be recommended. Selective incapacitation, however, relies on the assumption that these chronic offenders can be reliably identified before they are involved in an extensive number of offenses, something that has proven to be a difficult prospect (Gottfredson & Hirschi, 1986). Blumstein and colleagues did not dispute the difficulties in identifying these career criminals but suggested that they remain a valid topic of criminological inquiry.

Forecasting Crime Rates

Age has also become a major factor in explaining changes in crime rates over time and in forecasting future crime trends. For whatever theoretical reason, scholars have concluded that the age-crime curve reflects changes in the prevalence of offending among certain age groups. It is logical, then, that changing numbers of adolescents and young adults in the population should produce corresponding changes in crime rates (Phillips, 2006). This provides the

potential opportunity to forecast changes in crime trends based on the age distribution of the population (Marvell & Moody, 1991).

Some research has suggested that the dramatically increasing crime rates during the 1960s and 1970s were attributable, at least in part, to demographic changes in the age structure of the population. Steffensmeier and Harer (1999) also suggested that the decline in crime during the first half of the 1980s was partly due to the declining population of teenagers. During this time, the sizable population of Baby Boomers was moving out of the most crime-prone years (i.e., aging out of crime). However, Marvell and Moody (1991) noted that although forecasts suggested a massive decline during the 1980s as the Baby Boomers aged out, the decline occurred for only the first half of the decade. Crime rates then increased again to record highs in the early 1990s even as the size of the teenage population declined (Fox, 1996; Marvell & Moody, 1991). Despite this confusion and apparent complexity in using age to predict crime rates, the declining crime rates during the 1990s were again attributed largely to the declining population of young adults (Steffensmeier & Harer, 1999).

In 1999, Steffensmeier and Harer found that changes in the age composition of the population did not appear to account for changes in crime rates as measured by both the Uniform Crime Reports and the National Crime Victimization Survey. Phillips's (2006) cross-national research also finds no real relationship between the size of the youth population and crime rates. Most important, she found that the relationship between the percentage of young people in the population and homicide is attenuated when other criminogenic social conditions (e.g., low social control, high economic deprivation) are present. She suggested that the relationship between age and crime is complex and that the exact nature of the relationship depends on other social and cultural conditions. Levitt (1999) also concluded that, although forecasting crime rates on the basis of the number of teenagers in the population may be a logical assertion, the magnitude of the impact of age structure on crime remains unclear. His research suggests that changes in the age structure of the population account for no more than a 1% change in crime rates per year.

Marvell and Moody (1991) argued that demographic changes should not be used to forecast crime trends, because the age-crime relationship may not be strong enough to base predictions on, and other criminogenic forces may be more important. Despite the apparent complexity of this relationship, scholars and the popular media continue to forecast trends in crime rates based on the age structure of the population. In 1996, for example, Fox pointed to a “demographic time bomb” of crime and violence related to the increasing population of adolescents and young adults expected through 2010. This echoed earlier suggestions that a new crime wave would be fueled by a new, large generation of “super-predators” (Steffensmeier & Harer, 1999). By 2005, the teenage population was expected to reach its largest size

in three decades (Fox, 1996). However, crime rates declined substantially throughout the decade of the 1990s and remained low in the early 2000s (Steffensmeier & Harer, 1999). Marvell and Moody (1991) summarized this difficulty by concluding from their review of 90 studies that “the age/crime relationship is far from established” (p. 251), limiting its utility in predicting future crime trends based on the age distribution of the population.

Conclusion

That the age–crime curve is a well-known and consistent correlate of crime often is taught as one of the major facts of crime in criminology courses. Yet the implications of the age–crime relationship for research methods, criminological theory, and practice remain a subject of debate. Largely prompted by Hirschi and Gottfredson’s (1983) strong assertions about the age–crime curve, scholars have continued to argue about its implications. Although Hirschi and Gottfredson argued that explanations accounting for the age–crime pattern are unnecessary, other scholars find various components of the criminal career to be relevant and fruitful avenues for research. Research in this tradition has increasingly turned to longitudinal designs, and theories specifically built around explaining the age–crime curve have become popular in recent years. The practical and policy implications of the curve have proved to be more difficult. The relationship between age and crime is complex, and researchers will likely continue to explore the various issues raised in this chapter.

AGGRESSION AND CRIME

KEVIN M. BEAVER

Florida State University

One of the most consistently documented findings flowing from criminological research is that approximately 5% to 6% of the U.S. population commits more than 50% of all criminal offenses. This small cadre of offenders is often referred to as *career criminals* or *habitual offenders*, to capture their prolonged and frequent involvement in criminal offenses. Even more striking than the sheer volume of crime committed at the hands of habitual offenders is their widespread use of physical violence. Compared with other criminals, career criminals are more likely to use serious violence; they also use physical aggression much more frequently. Rape, robbery, assault, and murder, for example, are crimes that are almost exclusively confined to habitual offenders. In all respects, then, career criminals represent the most serious violent offenders, and they also pose the greatest danger to society.

Career criminals are thus very different than all other offenders in terms of their frequent involvement in crime as well as their frequent use of aggression. The questions that come to bear, then, are the following: (a) What are the factors that contribute to the development of habitual offenders, and (b) are these the same factors that contribute to the development of all other types of offenders? The answers to these questions are obviously complex, but rich insight can be garnered by focusing on two intertwined issues. First, the use of aggression appears to be one of the main elements that distinguishes chronic offenders from

other offenders. Second, and closely related, the making of criminals is a sequential process that begins at conception and continues throughout the rest of the life course. Any understanding of chronic, habitual offending, therefore, must begin by unraveling the developmental origins of aggression. This chapter explores these issues in great detail and examines the close nexus between aggression and crime.

Defining Aggression

Before moving into a discussion of the development of aggression and how it relates to crime, it is first necessary to arrive at a definition of *aggression*. Many types of behaviors can be categorized as aggressive. Lying, stealing, and vandalism are often used as visible indicators of aggression. Although disruptive and socially annoying, these types of behaviors do not necessarily constitute acts of aggression, and they certainly are not harbingers of chronic offending in adulthood. As a result, scholars often divide aggression into different components, each reflecting a relatively homogeneous set of behaviors. The underlying assumption is that different types of aggression may have different etiologies and may differentially relate to the odds of engaging in offending behaviors later in life.

One of the main distinctions made by scholars trying to define aggression is delineating indirect aggression and

direct aggression. *Indirect aggression* is usually verbal and covert and includes actions such as gossiping and ostracism. *Direct aggression*, in contrast, is typically physical and overt and includes behaviors such as hitting, kicking, punching, and biting. In general, females are more likely than males to use indirect aggression, and males are more likely than females to use direct aggression. Although both forms of aggression have important ramifications, it is direct aggression that is most applicable to the etiology of criminal behaviors. As a result, this chapter focuses exclusively on direct aggression.

Simply focusing on direct aggression leaves open a lot of room for ambiguity and treats all forms of direct aggression as the same. For example, consider two men, both of whom engaged in a serious physical fight in the past week. Unprovoked, one of the men attacked an elderly woman. The other man, in contrast, was jumped by a group of teenagers and fought back in self-defense. These two types of direct aggression clearly are different, and thus it is essential that the definition of aggression be able to delineate between the two. In the preceding example, the behaviors were the same: Both men were fighting; however, the intentions were quite different. For one man, using aggression was a way of inflicting harm on someone, whereas for the other man, using aggression was a defense mechanism. To take differences in intentions into account, this chapter defines aggression as direct aggression whereby the actor intends to inflict harm on or intimidate another person.

The Development of Aggression

One of the most firmly established criminological findings is the age-crime curve, which captures the age-graded nature of delinquency. The age-crime curve resembles an inverted *U*, whereby delinquent involvement does not exist until around the age of 12, then rises sharply until around the age of 18 or 19, at which point it begins to decline relatively quickly. By age 30, rates of criminal involvement hover near zero and remain that way throughout the rest of life. The age-crime curve has been observed at different time periods, in different countries, and by means of different methodological techniques—it is, in short, a robust criminological finding. As a direct result, there has been little reason to suspect that the age-crime curve may not be painting an accurate picture of the ebb and flow of delinquency over time.

Part of the reason that there has been little dispute of the age-crime curve is because most criminologists study adolescents and adults but fail to investigate antisocial behaviors among children. After all, how could children commit crimes such as rape, robbery, or assault? This is, of course, a rhetorical question; children do not—in fact, they cannot—commit these types of crimes. However, they can begin to display signs of antisocial behaviors, and they can engage in various forms of aggression during the first year

or two of life. The problem, however, is that this section of the life course has not been studied extensively among criminologists. In recent years, a small group of researchers, spearheaded by Richard Tremblay, have examined the use of physical aggression among children (Tremblay, 2000, 2006; Tremblay et al., 1999). Their scholarship has pointed to the possibility that theory regarding the age-crime curve may perhaps need to be revamped.

Tremblay and his colleagues have examined aggressive behavior in very young children and tracked them throughout childhood. The results of their studies have been quite striking. They have found that some children begin using aggression, including hitting and kicking, well before their first birthday; in some cases, around 7 or 8 months of age (Tremblay, 2000). Even more revealing is that Tremblay et al. have reported that more than 80% of children began using physical aggression by age 17 months (Tremblay et al., 1999). Within childhood, the peak age at which children use aggression and violence is around 2 to 3 years, after which rates of aggression decline until mid-adolescence. Other types of antisocial behaviors that are not necessarily aggressive per se are also almost universal behaviors among children. For example, Tremblay and associates (1999) found that approximately 90% of children took things from others. With age, all of these types of behaviors become less prevalent.

Against this backdrop, Tremblay and others have argued that there are really two distinct age-crime curves (Tremblay, Hartup, & Archer, 2005). The first, the traditional age-crime curve described earlier, is based on official crime measures and captures involvement in law-violating behaviors. The second age-crime curve measures not criminal involvement per se but rather physical aggression. This age-crime curve also resembles an inverted *U*, whereby physical aggression does not appear until around the age of 1, then increases sharply until around age 3, declining quickly thereafter. Keep in mind that this latter age-crime curve indexes only acts of physical aggression, not official acts of crime or delinquency.

The fact that there are two age-crime curves is a somewhat new finding, and the next logical question is whether these two age-crime curves are interrelated or whether they are distinct from each other. Before tackling this issue, it is first necessary to determine whether behavior is stable and what is meant by *behavioral stability*. There are, in general, two types of stability: (a) absolute stability and (b) relative stability. It is easiest to make the distinction between these different types of stability clear by providing an example. Suppose a group of children was examined when they were 10 months old, again when they were 18 months old, and again when they were 24 months old. Suppose, further, that at each of these three ages, they were assigned an aggressiveness score (based on a valid measure of aggression) that ranged from 0 to 10, with higher scores representing more aggressiveness.

In order for absolute stability to be preserved, the scores for each person must remain the exact same at each age. For example, if a child received a score of 3 on the aggression scale at age 10 months, that child must also receive a score of 3 on the scale at age 18 months, and he or she must also receive a score of 3 at age 24 months. Any change in the value of the aggression scale across time would reduce absolute stability. Perfect absolute stability, where everyone has the exact same score at each age, is rarely, if ever, observed in the social sciences. However, it is possible to approach perfect absolute stability in some instances. *Absolute stability*, in short, measures the degree to which people have identical scores on some measure over time.

Relative stability, in contrast, compares all people being assessed (on the aggression scale, in this example) and rank orders them. So, for instance, suppose that there were three children who were once again assigned an aggressiveness score (again, based on a valid measure of aggression) when they were 10 months old, 18 months old, and 24 months old. At each age, it would be possible to rank order these three children, whereby one child would be rated as the most aggressive, another would be rated as the second most aggressive, and the last would be rated as the least aggressive (or the third most aggressive). Relative stability is achieved when the rank ordering of people does not change over time. In the current example, the most aggressive child at age 10 months would also be the most aggressive child at age 18 months, and he or she also would be the most aggressive child at age 24 months. With relative stability, then, change is possible on an absolute level, as long as the rank orderings remain the same. In reality, perfect relative stability is rarely, if ever, achieved, because there is usually at least some change in the rank ordering of people.

The distinction between absolute stability and relative stability is critical, especially when one is examining behaviors over the life course. After all, the frequency with which aggression is used varies drastically across different stages of the life course, and just because someone uses aggression on a daily basis at the age of 18 months does not necessarily mean that he or she will also use aggression on a daily basis at age 35 (absolute stability); however, it is quite a different question to ask whether the most aggressive 18-month-old will mature into the most aggressive 20-year-old (relative stability). In this case, an 18-month-old might use aggression daily, which would make him or her a highly aggressive child. As an adult, however, this individual may not use aggression as frequently and instead may resort to aggression perhaps twice a month. If this is the case, then as an adult this person would still rank near the high end of the aggression spectrum. It is clear that his or her use of aggression has dropped appreciably from an absolute stability perspective, but from a relative stability perspective this person remains one of the most aggressive persons when compared with other adults. From a developmental standpoint it makes more intuitive sense to speak in

terms of relative stability when one is examining the stability of behavior over time. As a result, for the most part when criminologists speak of *stability* they are referring to relative stability, not absolute stability, and in this chapter stability should be equated with relative stability.

A wealth of studies have examined the stability of anti-social behaviors, including violent aggression, over long swaths of the life course, and the results have been remarkably consistent. Across samples, generations, and countries, and regardless of the sample analyzed and the methodological techniques used, extremely high levels of relative stability in aggressive behaviors have been observed. In a classic article, Dan Olweus (1979) reviewed studies that had examined the stability of aggressive behavior over time; he found that aggression was extremely stable, even more so than IQ scores. Findings from more recent reviews have upheld Olweus's original article by showing that aggressive and violent behaviors are highly stable across long periods of the life course. Persons with the highest degrees of stability, moreover, are those who score extremely high or extremely low on aggression. In other words, people who are the most aggressive (or the least aggressive) at one point in time are likely to be characterized as the most aggressive (or the least aggressive) at another point in time. Change, in other words, is highly unlikely. With this information in hand, it is probably not too surprising to learn that one of the best predictors of future criminal behavior is a history of aggressive behavior in childhood and adolescence.

Building on the studies that have examined behavioral stability, criminologists have also examined whether the age of criminal onset is associated with offending behaviors later in life (DeLisi, 2005). Age of criminal onset typically is broken down into two categories: (1) an early age of criminal onset and (2) a later age of criminal onset. Although there are many ways to operationalize an early age of criminal onset, most criminologists measure early-onset offending by examining the age at first arrest. Offenders who were arrested at or before age 14 are usually considered early-onset offenders, whereas those who were arrested after age 14 are considered as having a later age of criminal onset.

Results culled from an impressive body of literature have shown that offenders who have an early age of criminal onset are more violent and aggressive when compared with offenders who have a later age of criminal onset. Early-onset offenders, in contrast to later-onset offenders, engage in delinquent acts more frequently; commit more serious, violent offenses; and continue to commit criminal behaviors for a longer period of time, usually well into adulthood. By all objective standards, early-onset offenders have a much worse prognosis in terms of criminal outcomes than do offenders who have a later age of criminal onset.

One of the main pitfalls of measuring early-onset offending with official crime statistics (e.g., age at first criminal arrest) is that aggressive propensities begin to

emerge much earlier than the age of official offending. This is why Tremblay and others have argued that the age–crime curve does not necessarily portray an accurate picture of criminal involvement over time; instead, it ignores early childhood and pretends that this stage of the life course has no bearing on later-life aggressive conduct. With this in mind, it is now possible to return to the original question: Are the two age–crime curves related, or are they separate? According to Tremblay and others, the two age–crime curves are indeed intertwined, and in the following sections a number of different theoretical perspectives are presented that are able to shed some light on the link between early-life aggression, or the early age–crime curve, and later-life involvement in crime and delinquency, or the later age–crime curve.

Theoretical Perspectives Linking Early-Life Aggression With Later-Life Crime

Because early-life aggression is such a strong predictor of adolescent delinquency and adult criminal behavior, any sound theory must be able to explain the rise of aggression in childhood, how aggression in childhood is linked to later-life crime, and why most aggressive children do not become criminal as adults. Most mainstream criminological theories collapse when they attempt to provide an explanation for these known behavioral patterns. There are, however, a handful of theories that hold some promise in their ability to explain some of these patterns. Two of the more influential theories—at least within mainstream criminology—are Michael Gottfredson and Travis Hirschi's (1990) general theory of crime and Terrie Moffitt's (1993) developmental taxonomy.

Gottfredson and Hirschi's General Theory of Crime

In 1990, Gottfredson and Hirschi published a widely read and highly influential book titled *A General Theory of Crime*, in which they set forth a parsimonious and easily testable theory of crime. Unlike most criminological theories that focus almost exclusively on social factors, Gottfredson and Hirschi centered their attention on a psychological personality trait: low self-control. According to this theory, low levels of self-control are the cause of crime; delinquency; aggression; and analogous acts, such as smoking, drinking, and arriving late to class. Low self-control was defined through six different dimensions: (1) an inability to delay gratification, (2) a preference for simple tasks, (3) a penchant for risk seeking, (4) a preference for physical activities as opposed to mental ones, (5) an explosive temper, and (6) self-centeredness. Persons who score high on these six dimensions have, on average, relatively low levels of self-control and thus are at high risk for engaging in antisocial and criminal behaviors. A rich line of research has tested this proposition, and the results

have been strikingly supportive of the theory. Indeed, of all the existing criminological theories, Gottfredson and Hirschi's theory of low self-control is among the most empirically supported, and measures of low self-control are often the strongest predictors of delinquent acts.

It appears, then, that variation in individual levels of self-control is an important contributor to adolescent delinquency and adulthood crime. Still, the questions that remain are whether this theory can explain (a) aggression in childhood and (b) the link between early-life aggression and later offending behaviors. To address these issues, it is necessary to examine the nature of self-control.

Gottfredson and Hirschi (1990) maintained that self-control is engineered during childhood, typically by the ages of 8 to 10 years. Parents, according to the general theory, are the main agents responsible for shaping and molding their children's level of self-control. Specifically, parents who monitor their children, recognize their children's misbehavior, and punish their children's transgression will raise, on balance, children with relatively high levels of self-control. Parents who fail to engage in these parenting techniques will, in general, raise children with comparatively low levels of self-control.

If this part of the theory is correct, then it takes about 8 to 10 years for parents to shape a child's level of self-control. Moreover, it is not inconceivable to assume that most parents do not engage in much discipline before their children are approximately age 18 months. It is around this time that most children begin to display signs of aggression and consequentially is approximately the same time that most parents begin to punish and correct their child's misbehavior. Over the course of the next few years, at least according to the logic of self-control theory, most parents will continue trying to blunt their children's aggressive behaviors. Most children will respond to parental socialization, their use of aggression will subside, and between the ages of 5 to 8, their aggressive behavior will not be nearly as widespread as it was during early childhood. Parental socialization tactics thus might be able to explain the early age–crime curve set forth by Tremblay and his colleagues (2005).

During the time between childhood and early adolescence the use of aggression is not nearly as high as it was early in life. With the onset of adolescence, delinquent involvement begins to rise sharply to form the initial upswing in the more traditional age–crime curve. Proponents of Gottfredson and Hirschi's (1990) theory argue that variations in self-control can also explain this age–crime curve. Although not well understood, and rarely studied, there is some reason to believe that levels of self-control are, on average, at their lowest during mid-to-late adolescence, around the same time that delinquent involvement is at its pinnacle. Near the end of adolescence and during early adulthood, levels of self-control begin to climb, which corresponds to the rapid drop in delinquency participation rates. The precise reasons for why levels of self-control change over time, however, are not known.

Also, it is important to note that the general theory places a relatively heavy emphasis on the role that criminal opportunities play in transforming low levels of self-control into a criminal act. If there is no crime opportunity available, then no one—not even persons with very low levels of self-control—will commit a crime. Thus, it is possible that there are more crime opportunities available during adolescence (especially because youths are able to escape the constant surveillance of their parents) than earlier in life (between the ages of 8 and 12 years). If this is the case, then self-control theory may be able to explain at least part of the age-graded nature of adolescent delinquent involvement.

The preceding discussion highlights the possible ways in which self-control theory can explain both the early age-crime curve and the later age-crime curve. However, can this theory also explain the stability in antisocial behaviors over time, including the link between early-life aggression and later-life crime? According to Gottfredson and Hirschi (1990), the answer is a resounding “Yes!” To understand their explanation of stability it is important to remember that levels of self-control purportedly emerge by around the age of 8 to 10. Furthermore, according to this theory, after levels of self-control are established, they remain relatively stable over the remainder of the life course. This means that a child with relatively low levels of self-control will mature into an adolescent with relatively low levels of self-control, who in turn will develop into an adult with relatively low levels of self-control. Given that low self-control is the cause of antisocial acts, including aggression and crime, then children with low self-control will be at risk for using aggression and, because they will develop into adolescents with low self-control, they will also be at risk for using aggression in adolescence. In adulthood, persons with low self-control will be apt to engage in aggression as well as criminal acts.

To recap, according to the general theory, the reason that aggression is prevalent during childhood is because self-control has not yet been acquired. As children age and as their parents socialize them, they begin to accumulate much higher levels of self-control. This emergence of self-control is accompanied by a concomitant drop in aggressive behaviors. Of course, not all children develop high levels of self-control, and those children who are typified by low levels of self-control are, according to Gottfredson and Hirschi (1990), the same children who are at greatest risk for continuing to engage in aggressive behaviors in adolescence, and they are also at great risk for engaging in criminal conduct during adulthood. Gottfredson and Hirschi’s theory of low self-control has the potential to explain the link between early-life aggression and later-life law-violating behaviors.

Moffitt’s Developmental Taxonomy

Moffitt’s (1993) developmental taxonomy is one of the most influential criminological theories advanced in recent years. One of the theory’s most noteworthy contributions is

that, instead of treating all offenders as having the same developmental pathways, Moffitt recognized that there were at least two different types of offenders, each with their own unique etiology. The first type of offender, which she labeled *life-course-persistent* (LCP) offenders, begins to display signs of antisocial behavior, including aggression, early in life, often well before the age of 2. LCP offenders, according to the theory, persist with their antisocial behaviors throughout childhood and, during adolescence, they engage in all different types of delinquent acts, ranging from very minor (e.g., underage drinking) to very serious (e.g., assault and robbery). As adults, LCP offenders continue their violent behaviors and criminal conduct; as a result, they often spend a considerable amount of time incarcerated. Approximately 6% of all males are considered LCP offenders, and there is debate over whether there are any female LCP offenders. Although LCP offenders comprise only a relatively small percentage of the population, they make up a disproportionate amount of all crimes, and they are responsible for the majority of all violent crimes.

According to Moffitt (1993), two interrelated factors are responsible for producing LCP offenders. First, LCP offenders are born with neuropsychological deficits. These neuropsychological deficits can be the result of birth complications, exposure to toxins in utero, genetics, or a range of other factors. Second, LCP offenders are born into adverse, criminogenic family environments, where their parents may be abusive, cold and withdrawn, or emotionally detached. To understand how these two factors (i.e., neuropsychological deficits and an adverse family environment) work together to produce LCP offenders it is important to recognize that children born with neuropsychological deficits are often challenging to care for; they tend to be fussy and socially taxing, and they typically have difficult temperaments. Parents who are warm, loving, caring, and attached to their children are often in a position to override the problem behaviors displayed by children with neuropsychological deficits. Some children with neuropsychological deficits, in contrast, are born into criminogenic family environments where their parents are not well equipped with the necessary skills needed to overcome the difficult nature of their child. Over time, the family environment exacerbates the antisocial behaviors of children with neuropsychological impairments, thereby setting the child onto an antisocial pathway that ultimately culminates in the creation of an LCP offender.

Moffitt’s explanation of LCP offenders also has the ability to explain the association between aggression in childhood and crime in adulthood. LCP offenders show extremely high levels of behavioral stability, wherein early-life aggression is associated with serious physical violence in adolescence, followed by criminal involvement during adulthood. Moffitt explained the stable antisocial behavioral patterns of LCP offenders by focusing on transactional processes that occur between the difficult temperaments of LCP offenders and the environment. In

brief, aggressive temperaments propel LCP offenders into certain criminogenic situations. For example, highly aggressive children often have difficulties excelling in school, which may lead to difficulties excelling in school during adolescence. LCP offenders, because of their problems at school, may drop out or, if they do graduate, face career prospects that often are circumvented and not very promising. As adults, then, LCP offenders are somewhat “knifed off” from conventional society, thereby embedding them even further into an antisocial lifestyle where behavioral change is unlikely to occur.

Because only a small fraction of all persons would be considered LCP offenders, Moffitt was left to explain why rates of delinquent involvement are so high during adolescence. To answer this question, she identified a second class of offenders, which she termed *adolescence-limited* (AL) offenders. AL offenders do not display antisocial tendencies in childhood; neither do they engage in criminal behaviors during adulthood. Unlike LCP offenders, who engage in antisocial behaviors at all stages of the life course, AL offenders confine their offending behaviors to adolescence, and their delinquent acts are much less serious than those committed by LCP offenders. The types of delinquent behaviors that most AL offenders commit are relatively minor and mostly include status offenses (e.g., underage drinking, truancy) or other forms of minor delinquency (e.g., petty theft). Most youth would be considered AL offenders because the majority of adolescents dabble in delinquency but are not antisocial as children and never commit a crime in adulthood.

Moffitt (1993) provided a unique and provocative explanation for the factors that contribute to the development of AL offenders. Unlike LCP offenders, who suffer from neuropsychological deficits and an adverse home environment, AL offenders engage in delinquency because of what Moffitt called the *maturity gap*. The maturity gap, according to Moffitt, captures the disjuncture that exists between biological maturity and social maturity for adolescents. Most adolescents would be considered biologically mature in the sense that they are capable of reproducing. In historical times, youth around the age of 13 did, in fact, begin to marry and produce offspring. They were also afforded the same rights and privileges that were extended to adults. In other words, their biological maturity was matched to their social maturity. In contemporary times, in most industrialized countries, however, adolescents are subjected to a series of laws and rules that adults are not. These regulations limit youths’ ability to partake in adult behaviors. Adolescents in the United States, for example, are not allowed to drive a car until they turn 16 years old, they are not allowed to vote until they turn 18, and they may be required to attend school until a certain age. The end result is a gap between biological maturity (i.e., they are able to reproduce) and social maturity (i.e., society places limits on their privileges) in which adolescents are trapped.

The maturity gap creates dissonance in adolescents and, as a result, they search out ways (unconsciously) to reduce

the disjuncture between their biological maturity and their social immaturity. To do so, they turn their attention to LCP offenders. LCP offenders live their lives with a total disregard for rules. They skip school, drink alcohol, have promiscuous sex, and basically thumb their nose at any and all regulations that seek to limit their freedom. In many ways, then, they engage in minor acts of delinquency that are reminiscent of “adult-like” behaviors (e.g., drinking alcohol, not going to school). To reduce the maturity gap, AL offenders mimic these adult-like behaviors being displayed by LCP offenders. By doing so, AL offenders increase their social maturity and erase, at least in part, the disjuncture between biological maturity and social immaturity. As adolescents mature into adults, they begin to be afforded the same privileges that are bestowed to adults. Maturation thus eliminates the maturity gap and, consequentially, delinquent involvement decreases appreciably as adolescents become adults.

Moffitt’s (1993) theoretical perspective has the potential to explain the conventional age–crime curve, but can it also explain the newer age–crime curve discovered by Tremblay and associates (1999, 2005)? Even though Moffitt did not directly confront this issue when setting forth her theory, there is some reason to believe that the developmental taxonomy may be able to shed some light on the early age–crime curve. During childhood, LCP offenders obviously display various signs of antisocial behaviors, including aggression. According to Moffitt’s theory, however, AL offenders do not show any signs of aggression early in life. Thus, the developmental taxonomy is able to explain why LCP offenders use aggression in childhood, but it is not able to explain why almost all children, including AL offenders, use aggression. Moreover, Moffitt’s theory does lend itself to an explanation of why aggressive behaviors decline around age 3 only to reappear once again in adolescence. Overall, however, the developmental taxonomy provides some needed insight into how aggressive behaviors in childhood may be tied to criminal behaviors later in life.

Implications for Crime Prevention

Rates of recidivism (being rearrested after being released from prison, probation, or parole) in the United States and other countries are extremely high, often hovering around 70% to 80%. Criminals who are released from prison, as well as newly released probationers and parolees, are all at very high risk for committing another crime in the near future. This holds true even among offenders who complete intervention modalities, such as drug and alcohol abuse programs. Part of the explanation for why the United States is not very good at reducing crime is that intervention programs focus almost exclusively on adolescents and adults and ignore children. As this chapter has discussed, this is a serious oversight, because the roots of violence begin to take hold early in life, and early-life antisocial behaviors

remain relatively stable over time. Thus, it would seem logical to conclude that the best way to reduce crime is to prevent it from ever surfacing. This is exactly what the research tends to show. Although some programs that focus on adolescents and adults have been found to be successful at reducing recidivism, the overwhelming majority of such programs have dismal success rates—that is, recidivism rates are extremely high. There is some good news: Programs that focus on the critical time periods of childhood and infancy have been shown to be extremely successful at preventing crime.

To understand how it is possible to intervene in the lives of young children to reduce offending behaviors later in life, it is first necessary to recognize that not all children are equally likely to become habitual offenders. Career criminals, for instance, disproportionately come from impoverished, urban neighborhoods, from single families, and from families in which one or both parents have been arrested previously. A number of other factors have also been found to relate to serious, violent offenders, but the key point is that these factors can be used to identify families who are at risk for producing career criminals. This is precisely the information that early intervention programs use to seek out children who are at risk for future offending behaviors.

Perhaps the most well-known and most successful early intervention program is David Olds's (2007) *nurse-family partnership* (NFP). The NFP identifies mothers who are pregnant with their firstborn child and who are also from low-socioeconomic classes (typically, they are unwed adolescents). Although the original aim of the NFP was to reduce abuse, neglect, and negative birth outcomes, emphasis also has been placed on reducing antisocial behaviors among these children. This latter goal is an especially daunting task given that the NFP focuses on families that are at elevated risk for producing criminals.

Once the women agree to participate in the NFP, they immediately have a meeting with a nurse; this meeting occurs while the women are pregnant. There typically are approximately six to nine nurse visits while the women are pregnant. These nurse visits are designed to accomplish three goals. First, they are concerned with improving the outcomes of pregnancy by helping mothers improve their prenatal health. This entails educating women about the harms associated with drinking, smoking, and using drugs. Improvements in nutrition also are discussed. Note that this part of the NFP is consistent with Moffitt's (1993) explanation of LCP offenders because it targets known risk factors that interfere with healthy brain development and that are linked to neuropsychological deficits. Second, nurses attempt to improve the child's health and development by helping mothers learn about competent care. This part of the program focuses on parental socialization, such as reducing abuse and maltreatment, and increasing effective parenting tactics. Note how this part of the NFP is in line with Gottfredson and Hirschi's (1990) theory on the development of self-control, and it is also consistent with

Moffitt's explanation of LCP offenders. Third, the NFP attempts to help mothers after their children are born by promoting smart choices about education and employment. Nurse visitations continue to occur throughout childhood to promote positive outcomes.

To evaluate the effectiveness of the NFP, Olds (2007) used random assignment, whereby families were randomly assigned either to the NFP or to some other type of programs. To say that the results showed that NFP is effective would be a gross understatement. Compared with children who were placed into another type of program, NFP children accrued 61% fewer arrests, they had 72% fewer convictions, and they spent 98% fewer days in jail. These are truly remarkable gains, especially given that the NFP focuses on infancy and childhood and yet the effects are visible decades into the future. Contrast this with the fact that programs that focus on adolescents and adults rarely achieve such marked reductions in crime. Other early intervention programs, such as the High/Scope Perry Preschool Programs, have also been found to be very effective at reducing and preventing antisocial behaviors in the future (Schweinhart, 2007). The common theme that cuts across most effective intervention programs is that they are established very early in the life course and the earlier the intervention is implemented, the better the results.

Conclusion

The overarching goal of this chapter was to examine the association between aggression displayed early in life and acts of criminal violence committed during adolescence and adulthood. This discussion led to five key points. First, there is now a rich line of empirical research indicating that the use of aggression peaks during childhood, typically around age 3 years. Second, although the use of aggression usually wanes by late childhood, and is not a predictor of future criminal behavior, most violent offenders have long histories of aggression that can be traced back to early childhood. Third, aggressive behaviors are relatively stable, even across very lengthy periods of time. Fourth, the traditional age-crime curve that captures the ebb and flow of official delinquency in adolescence is complemented by a similar age-crime curve that captures the ebb and flow of aggression during early childhood. Fifth, research has revealed that the most effective intervention programs focus on at-risk families and implement prevention programs immediately after conception. In general, the earlier interventions are established, the larger the reduction in antisocial outcomes.

These findings have important implications for criminologists and for the criminal justice system. To begin with, less attention needs to be paid to offending during adolescence, and more attention needs to be expended on examining the development of aggression in childhood. As it stands now, mainstream criminological research typically

fails to study this important section of the life course and usually focuses narrowly on adolescence and adulthood. However, as an abundance of research outside of criminology has shown, childhood is perhaps the key stage of the life course in terms of the etiology of violent offending. More and more research needs to be directed at unpacking the development of aggression during childhood. Focusing research efforts on childhood advance the understanding of the causes and correlates of crime and delinquency. This important knowledge base then can be used to develop early intervention programs that are based on and guided by methodologically rigorous research findings.

The development of criminal behavior, as this chapter has discussed, is complex, involving a multitude of factors that interlock across time and space. To gain a complete picture of what causes offending behaviors to emerge, how they develop, and why they are stable is a daunting yet exciting enterprise. Insight into these issues is most likely to be garnered from research that takes an interdisciplinary approach and examines environmental and genetic influences on human behavior across the entire life course.

CITIZENSHIP AND CRIME

RAMIRO MARTÍNEZ JR.

Florida International University

The scarcity of research on Latinos and crime, citizens and noncitizens alike, is one of the most curious shortcomings in the development of race/ethnicity and social science scholarship. This oversight is interesting, because the 1931 Wickersham Commission report focused on police treatment of Mexican immigrants. Moreover, early research on Latinos and police by Julian Samora (1971) includes overlooked studies on Border Patrol mistreatment of noncitizens or illegal aliens and state police abuse of persons of Mexican origin in Texas. The contentious relationship between ethnic minorities and urban police departments during World War II was also highlighted by the “zoot-suit hysteria” and police misconduct in the 1940s, when the singling out of Latinos by various facets of the criminal justice system laid the foundation for protracted animosity between the Los Angeles Police Department (LAPD) and the city’s Mexican-origin community (Martínez, 2002). In fact, Edward Escobar (1999) contended that, even in the absence of solid data on this topic, the LAPD and general community stereotyped Mexican-origin youth as inherently delinquent or criminal aliens for the last half of the 20th century.

Even though early research on immigrants and the police exists, contemporary research on Latino perception of local police, U.S. citizen and noncitizen encounters with federal police agents (i.e., Immigration and Customs Enforcement agents), or city police by residents of heavily

immigrant communities across the United States is scarce. Scholars have understandably directed attention to black and white attitudinal differences toward the police and documented the perception and prevalence of police misconduct in some African American areas, in particular extremely poor communities, where aggressive police strategies are concentrated. Still, researchers interested in examining racial and ethnic variations in experiences with the police and other criminal justice agencies should extend attention to Latinos, because they are the largest immigrant group in the United States; also, almost one third are unauthorized, or illegal, making them one of the largest noncitizen groups in the nation.

This failure to conduct research is even more apparent when one considers that over the last two decades, social scientists have argued that not only is the Latino experience quite different from that of non-Latino whites and blacks but that distinctions also exist among Latino subgroups and gender. In addition to immigration and legality status, these include variations in terms of historical, cultural, political, demographic, economic, and religious patterns. Although a comprehensive discussion of these differences across the social sciences disciplines is beyond the scope of this chapter, it is important to recall that ethnic and immigrant groups require attention by criminologists. More important, a historical foundation on Latinos and crime exists, and that starting place should be used to inform contemporary studies while ensuring that

the incorporation of Latino citizens and noncitizens is a routine development in criminological research.

The purpose of this chapter, then, is to remind readers that noncitizens, especially Latinos and other immigrant group members, usually reside in economically disadvantaged communities. Sampson and Bartusch (1998) noted that legal cynicism and dissatisfaction with police were both intertwined with levels of neighborhood disadvantage, an effect that trumped racial differences in attitudes toward the police, even after controlling for neighborhood violent crime rates. Moreover, ecological characteristics of policing also include the use of physical and deadly force at the city level, officer misconduct in police precincts, and slower response times in communities, highlighting research that attitudes toward the police may be a function of neighborhood context. These actions hit young black males harder than others, but the impact on Latino youths is an open issue, as is the impact of recent immigration and the role of immigrant concentration in shaping police encounters. These issues potentially appear to construct a different story with respect to Latinos, violence, and the police.

This chapter closes with suggestions for future research. U.S. society is now composed of multiethnic populations, and the time has come to routinely examine Latinos in police research as well as differences within citizenship status groups, including naturalized citizens, legal residents, and unauthorized migrants. Pioneering research, together with early immigration and crime studies, includes issues relevant to Latinos and the police. Before addressing what we do and do not know about Latinos and police, the consequences of ignoring the Latino population is emphasized.

Why Is Research on Latinos Important?

The need to transcend the black–white paradigm of U.S. criminological research is obvious. Latinos comprise both native-born (60%) and foreign-born (40%) individuals, making them a very diverse group in terms of historical background, their manner of reception, and their year of entry into the United States. This last factor is important to acknowledge, because since 1960, the Latino population has experienced substantial growth due to rapid migration from Latin American countries and the Caribbean, along with high levels of fertility. Latinos are now the largest racial/ethnic minority group in the United States, meaning that the nation is as racially, ethnically, and linguistically diverse as it was at the turn of the 20th century, and the Latino population will likely continue to grow in the near future. Also, according to the U.S. census, the population of immigrants who are eligible for naturalization was 8.5 million in 2005; of these, more than one third, or nearly 3 million, were Mexican-origin Latinos (Rodríguez, Sáenz, & Menjívar, 2008). Thus, not only are Latinos of

Mexican origin are less likely to become U.S. citizens, but also the number of naturalized citizens from Mexico rose by 144% from 1995 to 2005—the sharpest increase among immigrants from any major country.

This growth has implications for the United States. Stereotypes regarding the Latino population proliferates in public discourse in the United States, fueled by media reports and perpetuated by some politicians. Most of these stereotypes go unchallenged even while they contribute to the notion that Latino immigrants are a dangerous threat to the nation. According to Leo Chavez (2008), these stereotypes include that Latinos are uneducated peasants, drug dealers, on welfare, and prone to commit crime. Moreover, new policy mandates for tightening the border and singling out illegal immigrants or criminal aliens, who are primarily of Mexican origin, are encouraged by politicians and commentators for the sake of enhancing national security. These mandates include the deployment of the National Guard, the building of a fence at the border between Mexico and the United States, and the labeling of undocumented immigrants as criminal aliens. Immigration policy now reflects national concern about local crime even though there is little systematic research linking these topics.

The failure to conduct research in this area also means that our understanding of this group, relative to whites and blacks, will be underdeveloped. This change requires researchers to consider whether Latinos are exposed to police tactics in a manner similar to black or white residents. If the groups are treated similarly, does immigration or legality status shape the manner in which Latinos are treated by the criminal justice system? As noted earlier, undocumented Latinos are now being targeted by local and federal police agencies, singled out from others in disadvantaged communities, which sets the stage for potential conflict between police and residents. Much like the neighborhoods studied by pioneering researchers in 1931, these activities are concentrated in economically disadvantaged communities, reminding us that economic conditions shape crime, violence, and perhaps police reactions to residents in some poor neighborhoods. However, the outcomes of criminal justice tactics are underexamined for Latinos, and many questions about Latinos and reactions to the police remain unanswered.

For example, although much of the Latino growth is in traditional settlement areas in the southwestern United States, there is substantial movement to places that are new Latino destinations or places where few Latinos resided in previous decades. Havidan Rodríguez and colleagues (Rodríguez, Sáenz, & Menjívar, 2008) noted that the emergence of anti-immigrant laws or ordinances have proliferated in these new destination points, aimed at preventing “illegals” from securing housing, punishing business owners, and allowing local police to search for “illegals” or to ask about legality status, an issue typically in the federal domain. Take, for example, the village of Hazleton,

Pennsylvania, which, according to the 2000 census, has a population of approximately 23,000 residents, about 5% of whom were Hispanic/Latino (Martínez, 2002). In 2006, local officials passed the Illegal Immigration Relief Act, a measure that would have resulted in racial profiling, discrimination, and denial of benefits to legal immigrants. This ordinance imposed fines of up to \$1,000 to landlords who rented to “illegal” immigrants, denied business permits to corporations who employed undocumented immigrants, and made English the official language of the village. Latinos bore the brunt of the latest anti-immigrant hysteria in Hazleton and other places that implemented similar restrictions. Thus, the consequences of anti-immigrant/Latino initiatives are that *all* Latinos, legality of citizenship status aside, are singled out by politicians and the media and are presumed to be in the country illegally.

It is important to note that not only is the composition of the Latino population (e.g., Mexican, Cuban, Puerto Rican, Salvadoran, Dominican) unlike that of most other racial and ethnic groups but also that the Latino population differs from earlier immigrants. The Latino population is growing and is estimated to represent about one quarter of the U.S. population by 2030 (Chavez, 2008). Although they are still concentrated in the southwestern states, Latinos are also drawn to other regions of the country, and they work in diverse sectors of the economy. Last, they are connected to their home countries, and many send money back to their country of birth. Remittances or money sent from immigrants in the United States is an important source of revenue for many countries in Latin America and the Caribbean. A decline in this revenue is ominous and shapes interactions with others left behind as well as Latino immigrants’ absorption into U.S. society. It also potentially creates more poverty in the home country.

Historical Background

This chapter is a reminder that early research on Latinos/immigrants has not adequately informed contemporary criminal justice studies. F. Arturo Rosales (1999) contributed to the nascent body of research on Latino crime and policing and made an important contribution toward our understanding of early-1900s immigration trends. This included how Mexican immigrants responded to the U.S. criminal justice system and to crime and violence within that system as well as immigrants’ reaction to non-Latino white hostility, which emerged during the era of massive Mexican immigration in the 1890s to 1930s. In other words, early border problems, such as the smuggling of liquor, drugs, and illegal immigrants, persist in contemporary society, as do concerns about an emerging “Mexican problem”—a stereotype that assumes an innate propensity to crime in newcomers who hail from south of the Rio Grande. This stereotype is still reflected in contemporary society by politicians and the media and now targets illegal

immigrants, a demographic group most likely to include persons of Mexican origin.

Regarding policing, some scholars contend that immigrant Mexicans experienced the negative presence of the police system as soon as they landed on the U.S. portion of the border. For example, drawing on historical data, including the 1931 Wickersham Commission *Report on Crime and the Foreign Born*, early researcher Paul Warnshuis (1931) noted that many Mexican immigrants were disproportionately arrested for disorderly conduct, a “color-less charge” used to “keep them in check,” and that “indiscriminate dragnets and brutal arrest tactics” were routine in Latino communities. These activities were undoubtedly linked to the widespread stereotype that Mexicans were inclined toward criminality. Warnshuis also quoted a Chicago police sergeant stating that “You know, Indian and Negro blood does not mix very well. That is the trouble with the Mexican; he has too much Negro blood” (p. 39), a stereotype that persists to this day.

In fact, the notion that Mexican Americans were “born criminals” has not only endured, but also, as Edward Escobar (1999) documented, eventually contributed to national concern about this group, culminating in harsh measures singling out Mexican youth and young adults. By 1943, many residents of the Los Angeles barrios believed that the LAPD regularly violated the rights of Mexican Americans and that police misconduct in the Latino community was routine. In one nationally publicized incident, between June 3 and June 10, 1943, white military servicemen, civilians, and policemen attacked Mexican American youth dressed in the distinctive zoot suits (suits with wide shoulders, thigh-length jackets, and tapered pants). Many were assaulted, shaved, and left naked in the Los Angeles streets. During the riot, LAPD officers allowed servicemen to beat and strip the zoot suiters, usually arresting the Mexican American youth for disturbing the peace. Police officers arrested only a handful of servicemen but jailed more than 600 Mexican Americans. With the police watching, servicemen entered bars, theaters, dance halls, restaurants, and even private homes in search of victims. By the end of the rioting, servicemen were targeting all Mexican Americans and even some African Americans. It is clear that, for some Latinos, hostility and animosity probably defined the relationship between the Latino community and the LAPD even long after the end of World War II.

The extent of this enmity, however, was largely ignored by criminology researchers as scholars in the United States directed their attention to race and crime for several decades, ignoring Latinos. This is unfortunate, because a research foundation existed that could be built upon to inform current research, including learning more from the well-documented police mistreatment of Mexican immigrants in the early half of the century. As early as 1919, the Texas Rangers, a state police force, were involved in “murder; intimidation of citizens; threats against the lives of others; torture and brutality; flogging, horsewhipping, pistol whipping, and mistreatment

of suspected persons; incompetency; and disregard for the law” (Gamio, 1971). The Texas Rangers were also routinely engaged as strike-breakers and took an active role in protecting employers’ interests. They interfered with the peaceful farmworkers’ strike of 1966–1967 and arrested persons without cause.

Julian Samora (1971) wrote that the Border Patrol regularly restricted or relaxed the movement of illegal Mexican aliens according to business cycles in the agriculture industry. The relaxation of immigrant policy, border-crossing enforcement, and the employment of “illegals” were linked to ebbs and flows in the U.S. border economy. When crops needed to be harvested, the Border Patrol participated in getting workers into the field. In contrast, when crop season ended and the workers were no longer needed, the number of apprehensions and deportations spiked. Thus, the periodic roundup of “illegals” was linked to agriculture industry policy and law enforcement practices.

Samora (1971) recognized that routine Border Patrol operations were shaped by concerted efforts to thwart “invasions of illegals” crossing the U.S.–Mexican border. Periodic moral panics created concern about the “growing number of Mexican aliens,” or a financial recession directed attention to the undocumented workers. There was also anxiety about perceived high levels of crime at the border and the potential of disease-ridden “aliens” crossing the border into the United States. During periods of heightened fear, Border Patrol officers saturated entry points; in 1952, they deported more than 500,000 undocumented Mexicans when the decision was made to close the border. As we now know, over time, the Border Patrol redirected its attention elsewhere, and the number of deportees dropped throughout the late 1950s and 1960s.

Thus, racial or ethnic conflict existed for some time in the southwestern United States. Present researchers should draw on work produced by early scholars. The hostile relationship between the Chicano/Latino community and the LAPD lingered for most of the 20th century, and the long-simmering tension from the LAPD zoot suit riot in 1942 can inform current scholars concerned with urban minority group crime, in particular those interested in the causes of urban riots and how police exacerbate racial–ethnic tensions, such as in the 1992 Los Angeles riots. The role that border police play in tightening up enforcement of immigration policy also is not new. The next section draws from a body of ecological research on race and crime and closes with suggestions for future studies.

Latino/Immigrant Neighborhood Disadvantage and Police Research

Much of the recent research on race/ethnicity and crime has been conducted at the aggregate level, on the basis of official data reported to the police. This literature does not ponder individual variations in propensity to engage in criminal

offending but instead considers variations in violent crime victimization or offending across places such as metropolitan areas or cities. Ecological research on crime and violence also draws attention to the relationship between race/ethnicity and place, whether that is the city, metropolitan, or community level, and proposes that racial disparities are linked to the varying social contexts in which population groups exist. A consistent finding in this literature is that violent crime rates, both offending and victimization, are higher in places with greater proportions of blacks or African Americans, and this finding persists over time. Most of these studies use homicide or violent crime rates or counts of racial/ethnic specific violence as the dependent variable, because homicides are routinely detected and reported to the police, but even these studies typically focus on black or white crime differences.

These aggregate-level studies have been valuable because they demonstrate the need to consider racial disparities in crime and in some cases encourage scholars to push conceptions of race and crime to include Latino composition in crime studies. Indeed, researchers have recently evaluated whether the neighborhood conditions relevant to black and white violence also apply to Latinos. At the forefront of recent ecological analyses of Latino violence is a series of articles based in the city of Miami, Florida, a heavily impoverished multiethnic city with large immigrant Latino and foreign-born black populations and high-profile inner-city communities (Peterson & Krivo, 2005). Latino-specific homicides were analyzed either alone or in comparison with models for native-born blacks and whites, and sometimes immigrant Haitians, Jamaicans, or Latino groups, such as the Mariel Cubans. All of these are racial/ethnic/immigrant groups that reside in high-crime and disadvantaged communities in need of police services, and that regularly encounter police officers, but the extent of positive or negative police–citizen interactions is not clear. Moreover, these Miami studies also noted that Latinos usually follow a pattern similar to that among blacks and whites in terms of the all-encompassing effect of concentrated disadvantage or heightened economic problems even though some predictors of Latino homicide are, to some extent, distinct. Thus, the basic linkages among disadvantage and homicide hold for African Americans, Haitians, and Latinos in the city of Miami, even in areas that are dominated by immigrants. This suggests that a need exists to further examine the interactions between police and residents and to explore levels of police treatment because, by extension, the study of Latinos and police encounters at the community level could vary from studies of blacks or whites.

This body of work is important because there is a strong relationship among economic disadvantage, affluence, and violent crime, and this connection has received a great deal of attention given the racial–ethnic differences in the strength of the association between crime and socioeconomic context at the community level. To a large extent,

this notion is rooted in Robert Sampson's and William J. Wilson's (1995) claim that the "sources of violent crime appear to be remarkably invariant across race and rooted instead in the structural differences across communities, cities, and states in economic and family organization" (p. 41), which helps explain the racial-ethnic differences in violence. The premise of this claim is that community-level patterns of racial inequality give rise to the social isolation and ecological concentration of the truly disadvantaged, which in turn leads to structural barriers and cultural adaptations that undermine social organization and in turn shapes crime. Therefore, race is not a cause of violence but rather a marker deriving from a set of social contexts reflecting racial disparity in U.S. society. This has become known as the *racial invariance thesis* of the fundamental causes of violent crime. Still, the racial invariance thesis has rarely been applied to ethnicity, crime, and policing. Although other conceptual or theoretical overviews on Latino crime and delinquency exist, attention is directed to macrolevel approaches, because this is where the bulk of Latino violence research is located.

The study of neighborhood disadvantage and violence has generated similar findings for blacks and Latinos in the border cities of San Diego, California, and El Paso, Texas. Other researchers have compared and contrasted the characteristics of black, white, and Latino homicides in Chicago; Houston, Texas; and Los Angeles or have controlled for social and economic determinants of crime thought to shape racial-ethnic disparities across neighborhoods (Peterson & Krivo, 2005). None have found evidence that more immigration means more homicides in a given area. For the most part, these studies also have led to the conclusion that the "disadvantage link" to homicide is similar for African Americans and Latinos.

Therefore, the impact of disadvantage holds in the case of Latinos on the border and might be extended to ethnic variations in terms of community-level causes of violence. By extension, it also appears that residents of heavily Mexican-origin communities might have enhanced contact with Immigration and Customs Enforcement agents concentrated on or around the Mexican border who are increasingly engaged in aggressive crime control strategies designed to stop the movement of undocumented workers into the United States. Much like the case of young African American males, perceptions of unfair and disrespectful treatment by law enforcement authorities, hand in hand with increased targeting by police in search of immigration violations and undocumented workers to deport, might influence Latino males' perception of police. As immigration crackdowns increase, young Latino adults are singled out regardless of citizenship status, which shapes their views of police and increases their distrust and negative interactions with criminal justice officials. The aggressive targeting by police typically occurs in extremely poor Latino communities and potentially strains relationships with community members and law enforcement officials.

This research discussed in this section supports the notion that structural disadvantage matters for violence

across racial, ethnic, and immigrant groups, and it should also matter for police treatment. However, research on neighborhood contexts and police encounters remains in short supply for Latinos. In short, future research should pay closer attention to potential variations across and within groups of various immigration status, ethnic variations, and perceptions of the police at the neighborhood level.

Recommendations for Future Research

A number of other important questions should be addressed in the future. For example, how does economic disadvantage operate to produce violence within and across Latino groups with varying levels of citizenship status but in similar communities? Also, is citizenship shaping ethnic differences in dissatisfaction with the police? Moreover, Latinos reside in areas with high levels of disadvantage, but many Latino communities have high levels of labor market attachment, even though typically it might mean employment in menial jobs. What happens when law enforcement officials target specific areas populated by working poor Latinos with aggressive policing tactics designed to subdue immigration policy violations but not necessarily crime? Will native-born Latinos be content with these tactics when pulled off the streets in these sweeps along with documented and undocumented immigrants?

It is not surprising that Latinos disapprove of recent stepped-up immigration enforcement. In a recent survey by the Pew Hispanic Center, Latinos reported wholeheartedly disapproving of a variety of enforcement measures (Menjivar & Bejarno, 2004). More than 80% said that immigration enforcement should be left mainly to the federal authorities instead of the local police; approximately 76% disapproved of workplace raids, 73% disapproved of the criminal prosecution of undocumented immigrants, and 70% disapproved of the criminal prosecution of employers who hire undocumented immigrants. Most Latinos agreed that there has been an increase in the past year in immigration enforcement actions targeted at undocumented immigrants, and more than one third of surveyed Latinos said there has been an increase in anti-immigrant sentiment. A majority of Latinos also reported worrying about deportation.

The potential rise of racial profiling among Latinos is an important topic to consider. In the Pew survey nearly 1 in 10 Latinos, both native and foreign born, reported that in the past year the police or other authorities had stopped them and asked about their immigration status. Thus, will Latino profiling increase hand in hand with police strategies disseminated in reaction to the growth of immigration across the United States? This tactic has the potential to create fear and distrust of the police in many Latino communities, where some families are blended, including immigrant parents and children born and raised in the United States. For example, the Border Patrol recently announced plans to check the documents of Texas residents in the Rio Grande Valley in event of a hurricane evacuation

before they are allowed to board evacuation buses. Some residents were concerned that this policy would encourage some people to not evacuate, further endangering immigrant communities and burdening agencies engaged in evacuation, rescue, and relief efforts.

This, of course, has a potential parallel in many immigrant communities. As immigrant blacks, such as Haitians in Miami, move into older African American areas, should we expect more or fewer negative encounters with police profiling in the cities of Miami, Miami Shores, North Miami, El Portal, Biscayne Park, and adjacent communities? Similarly, what about when whites were replaced by Haitians in these areas? These are neighborhoods or municipalities where the lack of attention to heavily immigrant black communities versus African American areas is another unfortunate oversight. Will border police, in search of immigrant blacks, profile African Americans, creating even more hostility in a community already resistant to police authority? Miami is an ethnically diverse community, with many Latino groups hailing heavily from the Caribbean basin. Perhaps cities such as Los Angeles and Houston, where the Mexican-origin population resides alongside Salvadorans and other Latino group members, provide yet another alternative scenario to the study of Latinos and police.

What is the impact of public or police corruption in the home country for Latino immigrants? It is possible that, as disadvantaged as conditions may be, that immigrants may use their home countries, which might have even worse economic and political conditions, as reference points when assessing their economic position relative to others, but the impact of these comparisons on police encounters requires more research. For example, research on human smuggling suggests that law enforcement officials actively aid in facilitating illegal immigrants' exit from their country of origin to the United States. Public officials openly request money and gifts to facilitate the immigration process to the extent that workers in the smuggling business consider public corruption a cost of doing business (Chavez, 2008). Even though they develop a general distaste for corruption and the extraction of bribes, which cuts into their profit margins, in the end public or police corruption is part of the price built into the smuggling business. These activities probably shape immigrants' perceptions, expectations, and tolerance of American law enforcement. It very well might be that an immigrant's prior experience in his or her home country has set such a low standard of expectation that it affects what he or she expects and will tolerate in the United States. Given the widespread popularity of immigration crackdowns, researchers should reconsider what works and what does not work when trying to improve police–citizen relations in Latino communities.

The growth of Latino populations across the United States has probably sparked an interest in increasing ethnic diversity among many police organizations; however, relatively few major departments are primarily Latino, and thus more research is needed on how the changing ethnic composition of these organizations influences the

relationship between race/ethnicity and crime. Communities of varying racial–ethnic makeup potentially have unstable relations with criminal justice organizations, especially in regard to police behavior. The extant literature has clearly provided a foundation on which to build an awareness of how Latino police officers interact with others beyond Miami, especially in the southwestern United States, where the history of racial–ethnic relations is very different from that in the rest of the country. Research on perceptions of police by family members, friends, coworkers, school mates, and neighbors of Latino residents who interact with law enforcement agencies routinely remains in short supply.

Conclusion

Scholars clearly should broaden their focus beyond blacks and whites to include Latinos with varying levels of citizenship status whenever possible in future research on police treatment and the criminal justice system. The growth of Latinos across broad sectors of U.S. society requires a renewed focus on multiple racial/ethnic/immigrant groups in the comparison of experiences with the police across a variety of communities and regions. Related to the growing ethnic diversity across the nation is the renewed concern about the influx of immigrants and the perpetuation of stereotypes on criminal immigrant Latinos by political commentators, policymakers, and residents in areas with growing immigrant Latino populations. The incorporation of Latinos will help scholars of violent crime, serious delinquency, and policing produce a broader understanding of the race/ethnic and violent crime linkages and expand that focus to include the diverse ecological contexts in which blacks, whites, and Latinos reside.

In addition, early scholars had an intimate understanding of the role Latinos and immigrants played in crime and police research in their era. Regrettably, that degree of familiarity seems to have disappeared from much of the recent criminology and policing literature, making it difficult for readers to benefit from the insights arising not only from the violent crime and disadvantage literature but also from other areas in the social sciences, especially the insights yielded by recent immigration studies. Until we bring Latinos and immigrants back into the study of crime, while considering citizenship status, our understanding of race/ethnicity will be underdeveloped at best.

WEATHER AND CRIME

DERRAL CHEATWOOD

University of Texas at San Antonio

Although questions about weather and crime, climate and crime, and season and crime are each different, they share a common assumption: that weather somehow influences criminal behavior. Many of the oldest beliefs about an association between weather and human behavior were based on otherworldly causes, ranging from weather gods to the positions of heavenly bodies. Astrology, which dates back 5,000 years, is a classic example of that approach. Other explanations, from Hippocrates some 2,400 years ago to Montesquieu in 1748, have assumed that the climate of specific areas influenced the populations living in those areas—for example, that hot southern climates produced hot-blooded people and cold northern climates produced cold-blooded people. Beginning in the 1800s, criminologists from Adolphe Quetelet to Cesare Lombroso argued that climate influenced the biology of the individual, which could lead the population of a given climate toward higher rates of crime. Most of those assumptions—in fact, pretty well all of them—have been discounted by recent scientific research. However, a number of modern theories of crime provide some well-reasoned arguments as to why weather and, by extension, climate and season, should quite logically be expected to influence criminal behavior.

This chapter defines what is generally meant by *weather*, *season*, and *climate*. It considers some of the theories that would lead one to expect a relationship between weather and crime and concludes that the routine activities theory of crime and theories that focus on stress in social

interactions offer the best explanations for the relationships seen. It then looks at the data that suggest that weather, climate, or season have an effect on crime. Finally, taking all this into consideration, it reaches some conclusions as to whether weather, climate, or season influence crime rates or crime patterns and if so, how.

Weather, Climate, and Season

There are actually three aspects of weather that have been studied in criminology: (1) weather itself, (2) season, and (3) climate. *Weather*, as defined in the *Glossary of Meteorology* (Glickman, 2000), is the state of the atmosphere of the earth, and the major components of that atmosphere that criminologists examine (and on which the local meteorologist reports) are temperature, humidity, precipitation, cloudiness, wind, and barometric pressure. The *Glossary* notes that *weather* commonly refers to short-term atmospheric conditions, usually thought of in terms of hours or days. Many of the modern studies of the impact of weather on crime use day-to-day changes in these weather elements as independent variables.

All natural events, including weather, occur in the dimensions of space and time. *Climate* is a pattern of weather characteristic of some given space, usually a large geographic area. Obviously, the weather will vary day to day and month to month both in southern Texas and in

northern Minnesota. However, just as obviously, the weather in southern Texas will characteristically be hotter and drier, and the weather in northern Minnesota will be colder and wetter. A pattern of weather characteristic of a period of time, usually months, that recurs with regularity from year to year constitutes a *season*. No matter what one day's weather may be, or what the climate may be, in almost all locations the weather changes during the year, being hotter during one period and cooler during another. The fact that the changing seasons affect human behavior patterns is confirmed by data on almost all human activity, including crime.

Because *climate* and *season* describe different aspects of weather, it is important to consider each of them separately when discussing the impact of weather on crime. Crime is a social behavior, and virtually every behavior in which humans engage is affected in minor or major ways by the weather that surrounds us, the change of seasons that change that weather, and the common weather patterns that define our climate. Both logic and a superficial review of crime data support the appearance of some relationship of weather to crime, and criminologists address questions about what the nature of that relationship is and how we can explain how weather either directly or indirectly brings about that relationship.

Theoretical Models of the Relationship of Weather and Crime

Early Explanations

Early philosophers believed that the weather had an effect on the biological and psychological makeup of individuals, and thus of cultures, with temperate climates making for temperate personalities and hotter climates making for more aggressive personalities. Characteristically, they argued that hotter days, hot seasons, and hot climates influenced individuals directly, making them less capable of controlling their inhibitions and more subject to impulsive and often aggressive behavior. Society, then, merely reflected those individual influences.

During the birth of modern social science in the 1800s, a Belgian statistician named Adolphe Quetelet formulated the *thermic law of delinquency*, which held that crimes against person are more common in hotter climates and seasons, whereas crimes against property are more common in cooler climates and seasons. During the rest of that century and into the 20th century, many of the first criminologists, from Cesare Lombroso and Enrico Ferri to Gustav Aschaffenburg, supported this thermic law. In the United States, some researchers blamed excessive heat for stimulating the emotions, increasing irritability, and bringing about lower levels of social inhibition, with a resultant inability to control one's impulses. All of these factors, they argued, led to the higher murder rates seen in the hotter

southern areas of the United States. This was carried further to a racist *climatic determinism* that argued that blacks, tracing their ancestry to the hot regions of Africa, carried a hereditary tendency to aggression and lower impulse control derived from that climate, which resulted in the higher murder rates among African Americans.

Others, however, rejected this biological determinism and began to observe that the correlation of weather and crime was mediated by culture and the changing nature of social interactions (Falk, 1952, provided an excellent review of this literature). In his comprehensive examination of suicide as a social phenomenon, one of the outstanding early sociologists, Émile Durkheim (1897/1951), countered these explanations and the thermic law of delinquency. Examining data on crime as well as suicide, he was one of the first scholars to bring a systematic scientific method to bear on the relationship of weather to crime. He pointed out that the patterns of personal aggression, both murder and suicide, that appear characteristic of certain climates at one time in history are not necessarily characteristic of those same climates at other times in history. He also demonstrated that within any climate different subcultures in the population will display different levels of aggression. It is, he argued, not the climate but the culturally framed social activity of the people who live in that climate that fosters or prevents aggression.

In examining seasonality, Durkheim (1897/1951) used data on Europe from much of the 1800s that did in fact indicate higher murder rates and suicide rates in the summer. However, after an analysis of those data, he concluded that it is not heat per se that brings about changes in the individual that lead him or her to commit murder or suicide. He argued that instead, the rates for those instances of premature or voluntary death occur during the summer because during that season social life is far more active, and social interactions are more intense. In noting this he was among the first to understand that the influence of weather, including seasonal or climatic effects, was indirect, bringing about changes in social interactions, which then changed the levels of crime and suicide.

Modern Theories

During the growth of modern criminology in the 20th century, theorists increasingly came to follow Durkheim's lead and examined how weather, climate, or season affects our day-to-day social interactions. Throughout the century, a variety of explanations were tested using increasingly sophisticated methods, and by the beginning of the 21st century two models had evolved to explain weather's impact on crime: (1) interactional theories focusing on stress and (2) routine activities theory.

Interactional theories look at the relationship of the individual to the social milieu in which he or she lives. In short, how do people manage to get along with each other day to day? In this model, stress—the need to constantly

adapt to changing conditions and accommodate others in social interaction—is a constant in all human behavior. We react and respond to our environment using socially learned habits of adaptation provided by our culture. That environment consists not only of other people and our interactions with other people but also the physical world. These adaptations usually are quite functional and allow the individual to deal with normal levels of stress. In cases of extreme weather, however, these normal adaptations are stretched beyond their functional limits, and normal physical, psychological, and social reactions begin to break down.

The way we are taught to accommodate increased stress brought about by hot weather, and even the way we are allowed to accommodate, is culturally, socially, and economically conditioned. In very hot weather in public work settings in the United States, men may take their shirts off. Women, by law and by cultural convention, may not. In very hot weather, middle- and higher-class people can stay inside their air-conditioned homes. The poor, unable to afford air conditioners and the energy to run them, cannot. In other words, the way groups of people are able to adapt to increased stress is based on everything from economic status to gender. During times of stress, these differences can result in increases in criminal behavior in some populations more so than others.

This stress is not all social or psychological. Heat has a very real physical impact on our bodies. During periods of increased heat we perspire, and blood flow is increased near the skin to better dissipate heat. However, at some point our bodies are physically unable to keep up with the stress produced by increasing heat (and accented by increasing humidity). Research has established that there are qualitative points, called *discomfort points*, at which heat (or the relationship of heat and humidity) begins to noticeably affect most people, and those points show up as having a relationship to some crimes, notably, assault and murder.

Beyond the biology of the individual, however, crimes are more often the result of stresses that derive from human interaction, and both weather and season change our patterns of behavior and thus, indirectly, the nature and level of stress to which we are subjected. These common patterns of behavior are called *routine activities*, and they are the focus of the second major approach to understanding the impact of weather and season on crime.

Routine activities theory, developed by Cohen and Felson (1979), is probably the most widely used model to explain the relationship of weather, climate, and season to crime. This theory holds that crime is the result of the convergence in time and in space of motivated offenders, suitable targets, and the absence of capable guardians. Note that it is not a causal theory that seeks to explain why individuals become motivated to commit crime; instead, it simply states that when people who might decide to commit a crime (or who are already intent on committing a crime) wind up at the same place and at the same time as people

or places that are suitable targets, and there are no other people or structures or props present that can protect those suitable targets, crime will increase.

Weather, climate, and season can have an impact on all three of those components (i.e., motivated offenders, suitable targets, and lack of guardians). The time around Christmas, for example, often finds us economically stressed, with an immediate need for cash to buy presents (or to pay bills from credit cards used to buy those presents). Field studies of armed robbers have revealed that robbery is often the result of a perceived need for immediate cash and that the preferred targets are individuals who are likely to have cash or valuables and unlikely to have a defensive weapon. Those two factors predominate around Christmas. Furthermore, the mass of shoppers in malls and in parking lots can overwhelm security personnel and normal security measures, leaving the suitable targets without adequate guardianship. And sure enough, FBI data confirm that robbery is the only Crime Index crime that is regularly more common in the deep winter months (December and January; Falk, 1952).

Even a look at the same type of crime, but different sets of victims, reveals that the common activities in which people engage are significant influences on the crimes they commit. McCleary and Chew (2002) examined seasonal risks for homicide but focused on victims who were children under age 15. They confirmed that the summer season peak found for adult victims was also characteristic of school-aged children, but for children under age 5 they found a significant peak in homicide victimization during the winter months. Most offenders in these child murders were young mothers, and the event precipitating the homicide was likely to have involved demands for food, clothing, or attention. These demands were most likely made at home, were more stressful for young mothers with less experience, and were accented during winter months, all of which explain the higher murder rates for young children during that season.

In research that compared routine activities theory with a more traditional psychological theory suggesting a direct association of temperature and aggression, Hipp and colleagues (Hipp, Bauer, Curran, & Bollen, 2004) found that routine activities theory was more effective in explaining the differences found in both violent and property crime. As we will see, data on a variety of different crimes over a number of years and in a variety of places support that conclusion. It is also important to point out that we have to be very careful not to confuse levels of scale when comparing a sociological theory such as routine activities theory with a biological or psychological theory. Even when considering stress, we have to be careful to make sure our data and our theory are derived at the same level of scale. Durkheim (1897/1951) pointed out that one should explain social facts only with other social facts. If we have data on crime rates that are derived from large population groups, for example, we have to be sure our theories are not reducing

our explanations for a group's crime rate to the psychological makeup of the individuals of that group.

Most modern explanations of how weather affects crime, then, rely either on a model suggesting that weather increases the level of interactional stress and pushes our culturally provided adaptations to their breaking point or one that suggests that weather has a role in changing the routine activities and patterns of social interaction, which changes the likelihood of crime. These theories are based on crime and weather data, and they are continually being tested by researchers using ever more detailed and extensive data sets. This research has yielded findings that do seem to be consistent as criminologists examine the impact of weather and season on crime.

The Data

First, there is no question that very extreme weather conditions affect crime patterns, just as they affect all other human activities. If a hurricane strikes a city with 100-mph sustained winds, burglary will go down during the hours that those winds are present. This is not because there are no motivated burglars in the city, or because there are no unprotected homes or businesses with valuables in them (in fact, there are probably more unprotected homes, because individuals with resources may have evacuated the area). The simple fact is that when it is impossible to walk on a street, the burglars cannot get to the homes. However, in a study of the impact of Hurricane Hugo, James LeBeau found that, once the hurricane had passed, there was a significant increase in calls to police for burglary as well as to report a "man with a gun," suggesting a possible increase in defensive gun use (LeBeau, 2002). When the motivated offender is able to move about, when suitable targets are available, and when the activities of guardians such as the police are directed elsewhere, crime increases.

In general, criminologists do not look at such extreme weather events. Instead, they conduct their research on the range of normal variations in weather factors, seasonality, or climate, and look for changes in crime patterns that relate to changes in those factors.

Climate

Although variations in climate and its effect on people served as explanations of differing crime rates in much of the early literature on weather and crime, the impact of climate on crime has been largely discounted. The earliest observations that led criminologists to suggest climatic impacts on crime were geographic differences in crime rates. In the United States, this was in particular the consistently higher murder rates found in the South. It is a fact that murder rates in the South have been higher than in any other region of the United States since data on crime have been collected. Examinations of the correlation of the South with

homicide rates has become progressively sophisticated over the past hundred years, and a significant debate has developed in criminology as to whether the association of murder and "Southern-ness" is due to cultural differences (particularly among minority populations) or to structural differences along economic lines. What is significant, however, is that in the dozens of scientific articles published on this question since the 1960s, climate is no longer considered as a possible explanation.

Research conducted by DeFronzo (1984) near the end of the 20th century may have effectively laid the climate and crime argument to rest. After controlling for nonclimatic variables, climate had only weak and indirect associations with crime rates. DeFronzo found that economic conditions, urbanization, and population demographics remain the primary predictors of overall crime rate (again, with the debate continuing over exactly which of the three carries the primary explanatory power).

From this, the research shifted initially toward seasonal effects on crime. Then, as computers gave us the ability to do increasingly complex research on increasingly large databases, criminologists turned to the examination of more precise, short-term weather factors.

Season

Quetelet's thermic law of delinquency argued that heat and violent behavior were related, such that violent crimes should be higher in the summer months and property crimes higher in the winter. A casual examination of Uniform Crime Reports data indicates that there is a considerable seasonal effect for both violent and property crime in the United States. However, when one looks at the Uniform Crime Reports for 1990 through 2003, it is obvious that the months in which the property crimes of burglary and larceny are highest are not in the cooler seasons but in July, August, September, and June (Hipp et al., 2004). Thus, a simple examination of the data challenges the thermic law. Research in other locations has also found seasonal patterns for particular crimes, although some of these patterns are not the same as those found in the United States. In England and Wales, robbery and burglary both increase in the winter, whereas personal crimes peak during the summer; in Ghana, the personal crime of assault is also highest between June and September. Landau and Fridman (1993) examined the seasonality of robbery and homicide in Israel and found that robbery followed a strong seasonal pattern of higher rates in the winter but that homicide, although somewhat more common during certain months, displayed no seasonal pattern (August was high, but July was low; March was high, but April was low). In the Southern Hemisphere, where the seasons are reversed, the patterns also are reversed. Studies of sexual abuse in Chile indicated that the months in which the number of cases were highest were November, October, and December (late spring and early summer in Chile), with

the lowest number of cases appearing in late autumn and winter during the months of May, June, and July (Tellez, Galleguillos, Aliaga, & Silva, 2006).

Indeed, in the United States, a temporal pattern in which certain months are significantly high and certain other months significantly low is apparent in almost all crimes. The problem is to determine whether the pattern variation is seasonal or monthly. This may sound like the same thing, but there is a difference, and it is a very important difference for theory, research, and policymakers. If one looks at American data over the past five decades, one can see that a number of crimes are highest in the warmer months of June, July, August, and September (Hipp et al., 2004). Larceny (theft), burglary, aggravated assault, and rape all have peaks in July and August, with the third highest month most commonly being either June or September. So, looking at American data we see a seasonal pattern for rape, assault, larceny and burglary, with all being higher during summer months. Because two of these are personal crimes and two are property crimes, they obviously do not support Quetelet's thermic law of delinquency.

Robbery and murder, on the other hand, show significant monthly patterns, but the months involved do not appear in any one season. July and August are also among the three highest months for murder in the United States, but the third most common month for high murder rates is December. This indicates a significant monthly pattern for homicide, yet it is clearly not a seasonal pattern. Also, robbery, which is considered a personal crime by the Uniform Crime Reports, is consistently at its highest during the months of December, January, October, and August (Cohn & Rotton, 2000).

What these data lead us to suspect, and research confirms, is that in any country the seasonal or monthly patterns characteristic of any crime are determined in large part by cultural patterns. In one of the most pronounced cultural effects, Zimring and associates (Zimring, Ceretti, & Broli, 1996) discovered that crime of all types drops by half in Milan, Italy, during the month of August, the month in which a large proportion of the Italian population goes on holiday. They noted that the opportunities for crime (suitable targets and the absence of capable guardians) do not decrease; in fact, there should be more unguarded homes and fewer guardians in place. The only conclusion that seems to fit their data is that "social processes unknown in American cities reduce criminal activity in Milan almost in half during the vacation month of August . . . Crime takes a holiday in Milan during August apparently because criminals take a holiday" (Zimring et al., 1996, p. 277).

In sum, the relationship between the hotter months of summer and a peak in rape and assault seems to be almost universal. However, although there is no such universal *seasonal* pattern for property crimes, robbery, or murder, many locations do show a pronounced *monthly* pattern for those crimes. Oddly, it appears that the thermic law of higher personal crimes in the summer and higher property crimes in the winter may hold for other locations, including

parts of Europe (Rotton & Cohn, 2002, p. 487), but not for the United States.

When we examine the data on season and specific crimes in more detail, the results strengthen the idea that the seasons act on crime by bringing about changes in routine activities and increases in interactional stress. Recall that July and August are the most common months for murder but that the third month in which murder is most likely to occur is December. Obviously, July, August, and December have drastically different weather patterns. However, these are the months in which we tend to take vacations as well as the ones during which we interact more frequently with friends and family. As many of us are aware, those people who can cause us the most stress—who can really push all our buttons—are the same people to whom we are closest. These months also see an increase in alcohol consumption. Alcohol releases inhibitions and can increase aggression, and it is a common drug of abuse among young males, who constitute the group with the highest murder rates (as both offenders and as victims). Increased interactions among people with strong emotional ties, which produce increased stress, and the increased use of alcohol by high-risk groups during the summer and over the holidays should be expected to increase the incidence of homicides, and that is what we see. It is not the weather characteristic of the season but the nature of social interactions that are influenced and changed by that weather.

This proposition is further supported when one compares seasonal patterns of murder and assault. Criminologists frequently make the argument that aggravated assault and homicide are "sibling" crimes; that is, they are the same behavior—an attack by one person with the intent to do serious bodily harm to another—and the only real distinction is whether the victim lives or dies as a result of the attack. If this is correct, then we would expect to see the same pattern of July, August, and December being the most common months for aggravated assault, just as we did for murder. However, that is not the case. The months with the highest reported cases of aggravated assault are July and August, but then June and September tie for third. Not only is December not one of the highest, but also it is consistently the month in which the lowest number of aggravated assaults are reported. On the one hand, that could mean that murder and aggravated assault are not the same behaviors at all, but it is also possible that assaults occurring around Christmastime are less likely to be reported because, as our theories suggest, they are more likely to occur between friends or members of an extended family. And that is exactly what happens when criminologists look at the reports made to police. The reporting of assault goes down near the holidays, often because fights between friends or family are hidden, but fights that result in a death cannot be hidden, and the number of murders increases. As Anderson noted as early as 1989, "It is probably the case that within families, assaults are relatively

unlikely to be reported to the police. Obviously, within-family [or within-friend] homicides cannot be correspondingly underreported” (p. 84).

In sum, it is not the weather characteristic of the season that directly increases aggression in individuals; instead, it is the social behavior characteristic of the season for each culture that changes the probability that criminal behavior may result, and this seems to apply across cultures. Most of the findings on the subject of weather and crime are based on American data, but research conducted in other nations suggests that although seasonal and weather effects on crime appear to be universal, the form they take is shaped by unique cultural patterns.

Weather

Although the results of research testing the impact of the full range of weather variables vary from study to study, there is fairly solid evidence for a relationship between crime and temperature, with lesser support for such a relationship between crime and humidity, precipitation, or changes in barometric pressure. A few isolated studies have found some impact of cloudiness, precipitation, or barometric pressure on crime, but most research using those variables does not. Only temperature seems to produce relatively consistent findings over the years (Rotton & Cohn, 2002, provided a good review of this research). Furthermore, temperature has been examined in a number of different ways. Basic raw temperature, as well as the discomfort produced by the addition of humidity in the *temperature humidity index* (originally called the *discomfort index*), have been tested. The temperature recorded at periods of time as short as 3 hours has been examined, as has the effect of consistently high temperatures over a number of days. Regardless of how it is tested, in one study or another, an increase in temperature has been found to correlate with increases in assault, homicide, rape, robbery, burglary, larceny, and domestic violence.

Studies that have examined the combination of weather effects and time effects on crime patterns have found that they are related. In line with routine activities theory, street crimes are consistently higher during weekends, when people engage in more leisure activities, have more time on their hands, are more likely to use alcohol, and are more likely to leave their homes for other entertainment venues. As a result, weekends are more likely to reduce guardianship for crimes such as larceny and burglary and are more likely to place demographic groups with higher propensities for aggressive crime (young males) in entertainment situations involving alcohol and in contact with suitable targets for aggression (anything from other young males to young females), with a concomitant increase in murder, aggravated assault, rape, and robbery. Temperature not only has a general impact on crime, but it also appears to compound or accentuate the impact that day of the week has on crime. Crime consistently increases on weekends,

but research shows that it increases more on hotter weekends than on cooler weekends. Taking this even further, LeBeau and Langworthy (1986) made the insightful observation that the increase in both crime and police calls for service during the summer months should thus not be considered unusual, “since vacations from work and school are primarily extended weekends” (p. 139).

So, routine activity models are strongly supported by both seasonal and weather data, but what about stress? Researchers looking at assaults in Dallas during the early 1980s divided neighborhoods into low status, medium status, and high status and found that the link between the discomfort produced by a combination of heat and humidity during the summer and an increase in aggravated assaults during that time was significantly more pronounced in low-status neighborhoods. This fits neatly with the argument that it is the ability to cope with increased stress and discomfort over time that provides a key to understanding the relationship between weather and assaultive crime. Increases in assault were associated with increases in the temperature humidity index across Dallas. All three classes of neighborhoods showed calendar variations, with some increase during summer months and a peak in assaults during the weekend, but the increase was significantly more pronounced in neighborhoods where economic disadvantage limited residents’ options to accommodate increased discomfort. In those low-status neighborhoods, during periods of increased heat, assault increased at a higher rate than in the more affluent neighborhoods because the poor “are less able to control the comfort of their home and work spaces and are perhaps more susceptible to the complex manifestations of heat stress” (Harries, Stadler, & Zdorkowski, 1984, p. 598).

In sum, most factors of weather—rain, snow, fog, weather fronts, barometric pressure, or wind—do not display consistent results when tested for their impact on crimes. Only temperature seems to be related, and the relationship is both robust and consistent across most studies of weather and crime or season and crime. Higher temperatures, or higher temperatures combined with higher humidity, produce such discomfort that our adaptations to stress are stretched to their limits. This discomfort also changes our patterns of routine activities in ways that place us at higher risk of both property and personal crimes. At the societal level, the impact of weather is further mediated by day of the week, the demographic structure and cultural matrix of the population, and the socioeconomic structure of the population. As with so many other things, our cultural, economic, and physical environments modify how we are affected, and how we respond to, everything we encounter.

Conclusion

Complex research on weather factors and crime across long periods of time or in numerous locales requires the

handling of extremely large data sets, and this has been possible only with the development of sophisticated data-gathering meteorological instruments; the advent of the computer; and the development of analytical techniques to handle large, complex data sets. As a consequence, and despite significant early studies conducted with the limited data and analytical techniques available, the study of detailed weather patterns and resultant crime changes is only a little over three decades old. In that short history there are some contradictory results in the research, often based on results obtained only for very limited geographic areas or periods of time. There are also a number of questions that have not yet even been addressed. Despite those problems, however, there do appear to be some basic conclusions we have reached that can be taken as a starting point for future research:

1. Of all of the weather variables measured, only higher temperatures, often augmented by higher humidity, show a consistent and robust relationship to crime.
2. In the United States there are pronounced seasonal patterns for rape, assault, burglary, and larceny, with all of these crimes increasing during the summer months. Other nations also display seasonal patterns for specific crimes, but they do not always have the same summer peak seen in the United States.
3. Both murder and robbery show regular monthly patterns, but not along seasonal lines. From this, it is important to understand that the impact of weather, whether seasonally or day by day, on any population is mediated by the culture, the social and economic status, and the demographic structure of that population.
4. The most effective model explaining the observed relationship between weather or season and crime is routine activities theory. Activities common to hotter weather or hotter seasons tend to directly or indirectly influence the probability of a convergence of motivated offenders, suitable targets, and reduced guardianship. Interactionist models that consider changes in stress produced by differing behavior patterns occurring in different weather situations or seasons also show promise in explaining changes in personal crime.
5. Climate as an explanatory variable for crime differences or the alleged criminality of any population has been largely discounted.

It is inherent to the nature of science that conclusions that are accepted at one point in time will change as more research is conducted to test those conclusions. Criminology scholars need to continue studying the relationship of weather and homicide in order to sophisticate theory, to test previous results with more accurate data and better analytical techniques, and to produce policy recommendations that can help reduce crime.

There is a need to improve criminological theories that address the relationship of weather and crime. Criminology needs better integration of the existing theoretical models, and there is a need to continue research that specifically tests

theories of the weather–crime relationship. Some studies have done this, but future research needs to develop very specific testable propositions that would enable us to integrate (or to distinguish between) two or more theories and then perform the research necessary to test those propositions.

We now have ever more complex and detailed data. Where early research often had only the number of crimes reported in some area over some period of time and, at best, daily weather data for those areas and times, modern technology can now secure hour-by-hour weather and crime data for any number of places over long periods of time. However, only improvements in theory can lead to more carefully selected data and more precisely targeted analysis. The research conducted from the 1970s through the 1990s began to explore the possibilities. Now, in the 21st century, criminology has enough consistent findings, much more sophisticated analytical techniques, and equipment capable of applying these techniques to massive data sets.

With all of this, further research is needed across broader geographic areas and over longer periods of time. We are becoming aware that weather “works” in interplay with temporal data, for example. We know that weather conditions can change the impact of time of day or day of the week, and we suspect this applies to major holidays as well. If some assumptions of interactional stress are correct, we need to begin to examine these interactions in more detail, including examining whether these weather and time interactions are different in hotter versus cooler climatic areas.

It is also significant for the future study of weather effects on crime that we are controlling our weather environment far more than we used to. We air-condition our homes, our cars, our businesses, and our places of entertainment. The data may be hard to obtain, but criminologists need to begin to consider what impact that has, particularly as it spreads (or fails to spread) to subgroups in our society, specifically, the poor. If these changes allow most people to mitigate much of the impact of increased heat and concomitant stress, but are not available to the poor, what impact will that have on crime rates in those neighborhoods in which crime is already a significant problem?

In this regard, criminologists need to begin to consider ways to apply the knowledge obtained. We cannot change the weather—at least, not yet. However, if we understand the impact of weather conditions on different areas, different times, and different populations, then we should become better able to prevent, or at least reduce, increases in crime resulting from this impact. It is possible that some of the most basic understandings of how temperature affects people’s routine activities or increases their levels of social stress, with resulting increases in crime, might enable us to act to head off some of those increases. We cannot yet put climate-controlled weather domes over our major cities, but with well-developed theory leading us to examine detailed data, we might be able to find some ways to address the weather–crime interaction with the technology we now have.

EDUCATION AND CRIME

GORDON A. CREWS

Marshall University

The purpose of this chapter is to provide an overview of the topic of education and crime. Although at first glance this appears to be a simple task, there is an inherent complexity to examining such a broad subject. There are many different perspectives from which a discussion of education and crime could develop. Criminologists might assume that a discussion of education and crime would comprise an overview of the impact that an individual's education level may have on his or her criminal or antisocial behavior. Alternatively, parents might assume it is a discussion of the impact of school violence and crime on the safety and learning of their children, and legislatures might assume it to be a comparison of the monies spent on fighting crime in the United States versus those spent to improve American schools. A novice might be expecting all or none of these approaches. This chapter attempts to address all of these views, albeit briefly.

The chapter begins with an overview of the generally accepted views about the relationships between education and crime. Given the volume of research on this topic, researchers have generally agreed on several basic specifics that they believe reflect the true relationship between crime and education. Next, this chapter attempts to clarify several points that need to be addressed initially. First, several general terms are defined (e.g., *education*, *educational attainment*, *intelligence*, *street smarts*, and *crime*) and then discussed as they are used in the study of the connections between education and crime. Finally, a discussion of how these terms intermingle is offered.

In order to develop a comprehensive framework from which to examine the concept of education and crime, two overall perspectives are addressed: (1) education's impact on crime and (2) crime's impact on education. It is hoped that through a discussion of these two general perspectives readers can develop an appreciation for the complexity of such a broad research area.

The concept of education's impact on crime is examined first. In this examination, education is in essence discussed as a definite inverse correlate between its attainment and criminal behavior; that is, as one (education) increases, the other (crime) decreases. A discussion of education's preventative nature is also presented, with a focus on its repressive nature in regard to initial criminal behavior and eventual recidivism rates. This examination involves a brief discussion of the connection between intelligence (IQ) and crime.

Crime's impact on education is also discussed as the second overall perspective in examining education and crime. In this discussion, crime is identified as a potential barrier to educational opportunity and attainment. Strong evidence supports the belief that criminal behavior and crime often block many people from beginning the educational process. That many others are prevented from educational attainment due to arrests, periods of incarceration, and past convictions/criminal histories also has strong empirical support. Finally, violence and safety issues in schools are briefly discussed in regard to the way they influence these subjects.

General Perspectives

Although the topic of education and crime may seem straightforward, there are many different viewpoints from which it can be examined. Researchers have studied this topic from many different perspectives. As a result of this research, several connections between education and crime have been introduced into the literature and are widely accepted. The following are a few of the empirically supported beliefs about the connections between education and crime:

- A person's lack of education often increases the likelihood that he or she will become involved in crime and antisocial behavior. The opposite is considered true as well: The more education an individual has, the increased likelihood that he or she will live a crime-free life.
- The lack of educational attainment generally decreases one's future employment opportunities because of increasing hiring standards in society, thus leading to possible criminal behavior for those individuals who cannot obtain viable employment.
- The lack of education and educational attainment generally limits one's IQ, thus making him or her more vulnerable to others for exploitation and potential secondary criminal involvement.
- The more educated a community is, the less crime it experiences.
- The more educated a person is, the less he or she fears crime, and the less it significantly affects his or her life.
- It is generally believed that increases in one's criminal behavior decrease his or her ability (and motivation) to complete higher levels of education (i.e., dropping out of school, getting expelled).
- History has demonstrated that increases in crime rates will almost always drain valuable resources from a community's educational needs and require that those resources be directed toward crime control efforts.
- History has also shown that an increase in local neighborhood crime very often decreases the effectiveness of local schools' educational programs and even student attendance.
- African Americans and Hispanics, overall, have less educational attainment than other racial groups. They also have a higher dropout rate than other racial groups. African Americans and Hispanics who drop out of school have a much higher rate of incarceration than those who do not. Research has empirically supported the theory that African Americans and Hispanics have higher rates of criminal behavior, and many scholars argue that there is a definite correlation between race and crime.
- On a practical level, one need only look at the fact that on days when school is in session, the level of property crime committed by juveniles decreases drastically.

Given these findings, it is difficult for many people to believe that, given that the United States has one of the

highest incarceration rates in the industrialized world, its rate of spending on educational systems is among the lowest. Many consider this to be one of the major catalysts for the ongoing increases in delinquent and violent behavior in America.

Definitions

To understand the possible connections and correlations between education and crime, one must first have an understanding of the essential parts of this discussion. These essential parts are actually definitions of several basic terms that people often use without giving much thought to their proper connotation. These terms may seem universally understood, but, as with many seemingly basic concepts, they have many different interpretations. In the sections that follow, definitions are provided for several key terms: *education*, *educational attainment*, *intelligence*, *street smarts*, and *crime*.

Education

The word *education* encompasses both the teaching and instruction and the learning of knowledge and information. This could involve the learning of proper social conduct and/or the absorption of technical competency. Simply put, education is one's ability to know something and his or her ability to then do something with this information. It very often focuses on the development of one's skills to work effectively in various trades or professions. It also involves the development of one's mental capacity, moral development, and global understanding.

Formal education consists of methodical instruction, teaching, and training by professional teachers, instructors, trainers, and professors, whereas informal education generally consists of instruction from parents, families, peers, or social interactions. The former consists of the application of pedagogy (i.e., strategies and/or styles of instruction) and the development of curricula (i.e., a set of instructional activities to offer instruction), whereas the latter consists of the social learning that a person gains from interactions with his or her intimate peer groups.

In evaluations of the topic of education and crime, education is most often viewed as something that one is given, has, or accepts, that influences his or her future behavior; that is, education is something that changes how a person views himself or herself and his or her environment. Education is generally viewed as a positive influence on one's behavior and life. It is widely accepted that the more education a person has, the more social that person's behavior will be, and the more opportunities he or she will have; he or she ultimately will have a better quality of life. A basic assumption in the field of criminology is that the higher a quality of life one experiences, the less likely he or she will be motivated to be involved in criminal or anti-social behavior.

Educational Attainment

Educational attainment is generally viewed as a measure of the amount of education a person has completed at any given point in his or her life. This usually involves a listing of the highest level of education a person has successfully completed (e.g., high school diploma, college degree). The term also can refer to any other type of technical learning that one may have, such as a technical certification or professional license.

In discussions of education and crime, educational attainment often is seen as an accomplishment that is believed to have a positive immediate or long-term impact on a person's prosocial behavior and success in life. The general view is that higher levels of educational attainment allow people more options for higher levels of employment. In turn, higher levels of employment generally lead to more income. The logic in this line of thinking is that the more income one has, the less likely he or she will be to seek criminal behavior or be interested in antisocial behavior.

Intelligence

Intelligence (also often referred to as *intellect*) is an all-encompassing term used to describe the capacity of one's mind and its associated abilities, including such human capabilities as the ability to reason, to plan, to solve problems, to think abstractly, to comprehend ideas, to use language, and to learn.

There are, of course, many ways to define intelligence. This is especially true when one is applying this trait to animal behavior, or even to plants. Some scholars argue that the concept of intelligence also includes such traits as creativity, personality, character, knowledge, and/or wisdom. Some have also argued that traditional measures of intelligence such as IQ tests, for example, are inadequate, because people can demonstrate intelligence in many ways. Some arguments claim that people can demonstrate their intelligence in eight different ways: (1) linguistic intelligence ("word smart"), (2) logical-mathematical intelligence ("number/reasoning smart"), (3) spatial intelligence ("picture smart"), (4) bodily-kinesthetic intelligence ("body smart"), (5) musical intelligence ("music smart"), (6) interpersonal intelligence ("people smart"), (7) intrapersonal intelligence ("self smart"), and (8) naturalist intelligence ("nature smart").

In examinations of education and crime, intelligence often takes on several interesting perspectives. Some people argue that extremely high and extremely low levels of intelligence often lead to criminal and antisocial behavior. Individuals with very high levels of intelligence can use their intellect to mastermind large criminal efforts, and those with very low levels of intelligence are victimized and often the pawns of these more highly educated individuals. Higher levels of intellect are often found in people who are involved in organized and white-collar crime (e.g., embezzlement), whereas lower levels of intellect are often found in disorganized and blue-collar crime (e.g., street crime).

Street Smarts

Although *street smarts* is not a very technical or academic term (some people consider it to be a slang term), many use it to describe the unique abilities possessed by many individuals. It often is used to describe a person who does not have much formal education (i.e., educational attainment), or a great deal of mental capacity or ability (i.e., intelligence), but who has a great or cunning ability to survive in almost any environment (especially in dangerous ones). The skills and abilities often demonstrated by people who have street smarts are things such as a unique ability to read others' body language and behavior. Such individuals also have the ability to understand the complexities of human behavior, drives, and motivations. Very often, these abilities are developed by people who need to survive in impoverished and dangerous neighborhoods that provide very little assistance or support to their inhabitants. Some people also call these skills *common sense*, that is, the ability to figure out what works and what does not work in any given situation without any formal instruction or study.

In examinations of education and crime, street smarts often are viewed as behaviors or abilities that lead a person toward criminal or antisocial behavior. Much of this view originates from the belief that most crime is street-level, or blue-collar crime; thus, it is activity most often engaged in by people living on the street who are either unemployed or employed in blue-collar positions. Many people would argue that common sense is something possessed by most law-abiding citizens but that street smarts are possessed only by the so-called criminal element.

Crime

Crime is most often defined as any breach of an established rule, regulation, or law committed by someone for whom a punishment may ultimately be prescribed by some governing authority or law enforcement body. Crime is also often defined as any deviant behavior that violates prevailing norms, specifically, cultural standards prescribing how humans ought to behave normally.

Academics often approach this topic through efforts to identify the complex realities surrounding the concept of crime. They seek to understand how changing social, political, psychological, and economic conditions may affect the current definitions of crime. Criminologists understand that this will affect the form of the legal, law enforcement, and penal responses made by any given state.

There are many different ways to classify crimes. A very basic method is to separate them into two types: (1) *mala prohibita* and (2) *mala in se*. *Mala prohibita* ("evil prohibited") crimes are those that are illegal because legislatures label and identify them as such. These are crimes such as seat belt laws, helmet laws, or gambling laws. The other type of crime is labeled *mala in se* ("evil in itself"). These acts, such as murder and sexual assault, are almost universally deemed harmful and negative.

In examinations of education and crime, crime often is viewed as acts committed by people who lack education; lack any educational attainment; and, most often, lack any higher level of intelligence. However, crime is a much more complex human experience and behavior than this view represents.

Education's Impact on Crime

The topic of education and crime can be approached from many different perspectives, so a framework for a basic understanding must be developed. The first area of discussion is education's impact on crime and criminal behavior. Although this issue is debatable, there is an overwhelming consensus among public officials, academics, teachers, and parents that postsecondary education is one of the most successful and cost-effective methods of preventing crime. Much of this consensus has been derived from the volumes of empirical research that has examined educational attainment as it relates to crime trends and public safety. Comparisons of state-level education data and crime and incarceration rates have consistently supported the fact that states that have focused the most on education (in general, financial support) tend to have lower rates of violent crime and incarceration. Although education can never be viewed as a "cure all" or magic bullet that will guarantee reductions in criminal activity or crime rates, research suggests that increased investments in quality education can have a positive public safety benefit.

Education as Crime Prevention

One of the most dominant ideas under the umbrella concept of education's impact on crime is the belief that a reduction in crime can most often be achieved by increased crime prevention and that the most effective form of crime prevention is achieved through education. Most people would argue that education can be an important element in preventing individuals from engaging in criminal behavior. Given the previous discussions in this chapter, increased levels of education generally lead to many other characteristics that are viewed as positive correlates of lessening one's criminal or antisocial behavior.

The literature generally offers two explanations for the preventive force of education on crime and antisocial behavior. The first is that education may change individuals' preferences (and, in turn, their breadth of choices). The second explanation is that education contributes to a lower time preference (i.e., learning the consequences of one's actions often make that individual postpone the direct satisfaction of needs). Some scholars argue that education leads to a lower time preference for consumption in the present (teaching one the potential negative aspects of immediate gratification) and a higher time preference for

consumption in the future (teaching one the benefits of working in the present to prepare for the future).

Many researchers argue that formal education (i.e., educational attainment) has a very strong impact on teaching students (through the study of history, sociology, and other subjects) on which they should focus more of their attention in the future. Formal schooling and instruction can communicate images of the situations and difficulties of adult life, which are inevitable future issues for all adolescents. Thus, educated people should be more productive at reducing the remoteness of future pleasures.

Many researchers also argue that the more education an individual has, the more heavily he or she will weigh the future consequences (i.e., punishment) of his or her current criminal or antisocial actions. If more education leads individuals to understand the benefit of delayed gratification, then people with a higher education should be deterred from committing criminal acts. It is believed that higher levels of education will make the immediate gratification of an individual's preferences and desires through criminal activities less important.

Most empirical studies have addressed the relationship between education and crime. Some have found that adolescents who are involved in paid employment or attend K-12 education are less likely to engage in criminal behavior. This suggests that a reduction in criminal behavior contributes largely to the social rate of return for the monies spent on education in the United States. There is much debate on the correlation between the money spent on education and the quality of education and its resultant overall impact on criminal behavior.

Not all studies find that more highly educated people are less likely to engage in criminal behavior, however. Some researchers argue that a country's average education level does not necessarily have a statistically significant effect on the number of violent crimes (e.g., homicides and robberies). As discussed earlier, many have also argued that increased levels of education actually facilitate the criminal behavior in some individuals because of their increased abilities and knowledge (e.g., computer fraud, pyramid schemes).

The following is a list of empirically supported findings about the connections between crime prevention and education:

- Most studies have found that graduation rates are generally associated with positive public safety outcomes and lower crime rates for communities.
- States with higher levels of educational attainment also have crime rates lower than the national average.
- States with higher college enrollment rates experience lower violent crime rates than states with lower college enrollment rates.
- States that make more significant monetary investments in higher education experience more positive public safety outcomes and lower crime rates.

- The risk of incarceration, higher violent crime rates, and low educational attainment are concentrated among communities of color, whose members are more likely to suffer from barriers to educational opportunities.
- Disparities in educational opportunities contribute to a situation in which communities of color experience less educational attainment than whites, are more likely to be incarcerated, and are more likely to face higher violent crime rates.

For most people, the connection between education and crime prevention is easy to see. Criminologists have spent centuries trying to determine the causes of criminal and antisocial behavior. A central component that emerges over and over is the idea of individual motivation and desire. Human motivation and desire are very complex natural occurrences, and they are difficult to understand, although most people would argue that it is easy to understand the connection between these traits and criminal behavior.

The Connection Between Intelligence (IQ) and Crime

Many trends have been supported by contemporary research that has examined possible connections between education and criminal behavior. That levels of education (higher and lower) are significant in the manifestation of criminal behavior has received empirical support, as has the notion that individuals with learning disabilities (and thus with lower education, intelligence, and coping skills) are more prone to violent behavior.

The major reason for these connections is the interrelated causal pattern of events that occur in learning, with education at the center. School achievement is generally predictive of *prosocial behavior*, designated as upholding the moral values of a society. Most people would argue that school achievement predicts prosocial behavior because in most societies academic achievement is interrelated with several other variables, such as financial success, high self-esteem, and an internal locus of control. This particular model may account for the reasoning behind the general idea that individuals with a high IQ generally have fewer tendencies for criminal behavior than individuals with a low IQ.

Investigations of the connection between criminal behavior and IQ often are based on the general hypothesis that having a higher IQ results in easier achievement in school. As stated earlier, doing well academically is associated with several societal factors as well. Individuals with a lower IQ may not succeed as much academically, which would result in lower self-esteem and not as much financial success, resulting in an increased disposition toward criminal behavior. This would seem to highlight the importance of stressing education and addressing issues of learning disabilities at an early age to prevent, or at least

mitigate, these negative attributes, thus preventing future criminal behavior and the resulting increased crime rates.

The connection between one's intelligence level and his or her criminal behavior is a very complicated and controversial area. Empirical research most often finds that IQ and crime are actually negatively correlated; that is, as one increases, the other decreases. Explanations for this generally fall into three approaches: (1) IQ and crime are spuriously, not causally, correlated; (2) low IQ increases criminal behavior; and (3) criminal behavior actually decreases IQ.

There are also popular arguments against IQ as a cause of crime. Some scholars argue that standardized IQ tests measure only middle-class knowledge and values instead of innate human intelligence. As a result, the fact that most minority groups and impoverished populations score lower on IQ tests simply reflects their diverse cultural backgrounds. These same groups also commit proportionately more crime because they suffer structural disadvantages, such as poverty and discrimination. Consequently, the same people who score low on IQ tests also tend to commit more crime, and so IQ and crime are empirically correlated. Thus, this correlation is not causal but reflects only culturally biased testing of intelligence (see Gardner, 1993).

A variation of this argument holds that the structural disadvantages that increase crime rates also reduce educational opportunities, thus lessening individuals' ability and motivation to score well on IQ tests. Many researchers argue that the IQ-crime correlation occurs only because both are rooted in structural disadvantage, which, in statistical terms, represents a spurious correlation at best. Although these discrimination-type hypotheses have wide appeal, they have received fairly little support in empirical studies, because IQ and crime are significantly correlated within race and class groups as well as when one statistically controls for race, class, test-taking ability, and test-taking motivation.

Another argument against IQ as a cause of crime holds that schoolteachers and administrators treat students differently according to their perceptions of the students' intelligence, thus giving negative labels and fewer educational opportunities to those whom they see as less intelligent. These labels and constrained opportunities in turn produce feelings of alienation and resentment that lead students toward delinquent peers and criminal behavior. As such, society's reaction to intelligence, and not any property of intelligence itself, increases criminal behavior. Unfortunately, few studies have adequately tested this labeling-type hypothesis (i.e., that deviance is derived from the labeling and mistreatment of certain individuals).

Education and Recidivism

Given the various aspects of this discussion, many people argue that the U.S. government should resume its long-standing policy of releasing a portion of Pell Grants

(student educational grants) and other types of financial aid to qualified incarcerated individuals. They argue that the benefits of such a practice (reductions in recidivism rates) will always far outweigh the public protests against such efforts (arguing that this reduces the funds available to nonincarcerated individuals).

The focus of the pro-grant arguments is that resuming this policy would drastically decrease rates of recidivism and save individual states millions of dollars each year. Again, there seems to be overwhelming consensus among many people that postsecondary education is the most successful and cost-effective method of preventing crime. However, this often becomes controversial when one starts applying these ideas to people who have already committed criminal acts. More than 1.5 million individuals are housed in adult correctional facilities in the United States. The U.S. Department of Justice generally portrays offenders as impoverished and uneducated prior to incarceration. Inside American prisons, many adult inmates are illiterate, and many more are functionally illiterate.

Most researchers would argue that social, psychological, and demographic factors correlate strongly with recidivism. Most persons are released from prison into communities unskilled, undereducated, and highly likely to become reinvolved in crime. Rates of recidivism in the United States are extraordinarily high. Although prison-based education has been found to be the single most effective tool for lowering recidivism, today these programs are almost nonexistent. Many would also argue that prison education is far more effective at reducing recidivism than are boot camps, shock incarceration, or vocational training.

In response to the American public's growing fear of crime and the call for more punitive measures to combat such fear, many legislators and policymakers have promoted building more prisons, enacting harsher sentencing legislation, and eliminating various programs inside prisons and jails. With rearrest rates increasing almost daily, it is clear that incarceration alone is not working in the United States. In fact, the "get tough" philosophy (originating in the mid-1980s), which pushes for more incarceration, punishment, and limitations of the activities available to prisoners, has often resulted in the elimination of strategies and programs that seek to prevent or reduce crime. As has been discussed repeatedly in this chapter, research has consistently shown that quality education is one of the most effective forms of crime prevention and that educational skills can help deter young people from committing criminal acts as well as greatly decrease the likelihood that people will return to crime after release from prison.

Despite this evidence of their extraordinary effectiveness, educational programs in correctional facilities have in many cases been completely eliminated. As of 2008, more than 1.6 million individuals were housed in adult correctional facilities in the United States, and at least 99,682

juveniles are in custody. The majority of these individuals will be released into communities unskilled, undereducated, and highly likely to become reinvolved in criminal activity. With so many ex-offenders returning to prison, it would seem clear that the punitive, incarceration-based approach to crime prevention has not worked as a basis for criminal justice policy in America. Therefore, it should not be surprising that so many people argue that the country needs to promote policies and procedures that are successful. Education, particularly at the college level, can afford individuals with the opportunities to achieve and maintain productive and crime-free lives and help to create safer communities for all.

Crime's Impact on Education

A second overall perspective on the concept of education and crime is to examine the impact of crime on education. As with education's impact on crime, crime's impact on education has several directions from which it can be approached. The following sections discuss crime as a barrier to educational opportunity and attainment as well as briefly consider school safety issues.

Crime as a Barrier to Educational Opportunity

One of the major areas in which crime's impact on education can be found is in how crime very often serves as a barrier to educational opportunity for many people. This barrier status can appear from two directions: (1) the negative mobility patterns for some groups in terms of traditional and nontraditional criteria for upward movement and educational achievement and (2) individuals' lack of opportunity for educational attainment due to their own criminal behavior (e.g., incarceration, dropping out of school, and expulsions).

For many people, going to college or achieving higher levels of education is an unrealistic goal because of financial constraints or living conditions; instead, daily survival is of utmost concern. Many of these individuals have had to drop out of school at an early age to help support their families and/or take care of younger siblings; for others, their own criminal behavior became a barrier to their future educational attainment. Incarcerated individuals obviously have very few opportunities (if any) above remedial instruction that generally leads to a GED. Others, because of their behavior, have been forced out of their local schools by suspensions and/or expulsions. As state budgets become more and more restrictive, educational programs in general have been eliminated or greatly decreased.

Crime's Connection to High School Graduation

As stated previously, many individuals are forced to drop out of traditional K-12 educational programs

because of their own criminal or delinquent behavior. These individuals usually start off with in-school suspensions, which evolve into out-of-school suspensions and, ultimately, to expulsions. In most states where the compulsory education age is 16, these individuals often find themselves forced to attend alternative educational programs. Research has supported the belief that the majority of these youth do not seek any postsecondary educational opportunities; many do not finish high school or GED programs.

Most, if not all, of the typical criminal or delinquent school behaviors, such as skipping school, drug use, violent behavior, and engaging in property crime, correlate strongly with a lack of high school graduation. Many educational systems across the United States have adopted a zero-tolerance policy stance when it comes to any type of negative student behavior. The primary result of these policies is expulsion from school of the delinquent child, and the primary result of most expulsions is that the individual never returns to school. Thus, lacking the proper educational attainment (and, possibly, intellect), he or she is not able to be competitive in most job markets. As stated earlier, a lack of employment is a major factor in an individual's decision to turn to criminal behavior to meet his or her financial needs.

School Safety Issues

A final area of discussion is the very practical impact that crime can have on education. The scope of this chapter does not allow a full examination of the issues related to school violence and its results, but it would be improper not to mention this issue at least briefly. Readers would be well advised to seek further information about the various impacts of school violence on students and teachers. There are volumes of research dealing with the most common forms of school violence: sexual harassment and bullying. These two issues alone, many people would argue, are responsible for a great deal of high school dropouts, assaults, and even school shootings.

School safety and the proper protection of students are very strongly connected to crime. The more crime a school has, the less safe the students are going to feel, and the less secure they feel, the less they will learn. When students have to worry about their safety on a daily basis at a school, the academic experiences very often get left behind. Most people would agree that learning becomes secondary very quickly when a child has to worry more about death than failure in the classroom.

Many of the connections that crime has with K–12 education relate to incidents that occur between students. There is a significant problem with bullying and sexual harassment on the campuses of many American schools. These acts, although not obviously violent, many times go unnoticed and can have an extremely negative impact on the victims. As previously stated, such treatment has been

connected to high dropout rates, failing grades, and even juvenile suicides.

Conclusion

It is extremely difficult to argue against the philosophy that substantial savings on the social costs of crime could be obtained by investing in education. Empirical research repeatedly has supported the theory that the likelihood of a person committing a criminal act decreases with years of education, although research also has found that the probability of committing some types of acts (e.g., tax fraud and embezzlement) actually increases with years of education.

It is also interesting to find that more highly educated people very often have more permissive attitudes and social norms toward criminal behavior. One possible reason for this is that they are confronted less frequently with criminality and are less likely to be victims of a violent crime. It is a known fact that criminality tends to be higher in areas where less-educated people live. A second reason for more permissive attitudes and social norms toward criminality might be that more highly educated people have a more liberal worldview in general. It also is a known fact that people with higher education generally earn more than less educated people and thus have a better, and safer, quality of life.

The potential benefits of, and access to, certain types of criminal behavior simply increase as one's earnings increase. Activities such as money laundering and insider trading often do not concern people who have no or very little funds. A second explanation is that more highly educated people are simply more knowledgeable and more informed about the possibilities of committing certain types of white-collar crimes. Thus, criminologists often point out that the key to white-collar or upper class criminal behavior is access (i.e., to funds, to inside information).

This is also true with blue-collar types of criminal behavior (e.g., shoplifting, vandalism, and violent street crimes). Research has supported the realization that most often these types of acts are committed by people with lower levels of education. One explanation is that people with less education have a "higher time discount"—that they see the future and calculate it differently than do people with more education. Moreover, they very often take into account the future consequences of their actions (punishment and sentencing) less than more highly educated people.

A final few notes on this subject should be pointed out from the discussion earlier about views on time consumption. It is argued that education leads to a lower time preference for consumption in the present and a higher time preference for consumption in the future and that, in turn, education very often teaches people to control their emotions (restraint and self-control). Most scholars hope that higher education attainment will lead to more intelligence,

which will lead to more understanding of the consequences of one's actions, whether positive or negative.

FAMILIES AND CRIME

LESLIE GORDON SIMONS

University of Georgia

This chapter brings together research and theory from criminology, psychology, family science, and sociology regarding the role of family processes in the etiology of delinquent and criminal behavior. Theory and research in the area of crime and delinquency have increasingly emphasized the importance of family processes in explaining the development of deviant behavior. Hirschi's (1969) social control theory, Sampson and Laub's (1990) life course perspective, Akers's (1973) social learning model, and Gottfredson and Hirschi's (1990) general theory of crime, for example, all identify parental behavior as a cause of delinquent behavior. Furthermore, criminologists have begun to focus on family-related issues such as marital violence, child abuse, and the manner in which romantic partners influence each other's involvement in antisocial behavior.

For the majority of Americans, the cultural ideal of the family emphasizes affection, consensus, harmony, and caregiving. There is, however, another side to families. Although families often function as an important source of nurturance and support, it is also the case that many categories of criminal and antisocial behavior are rooted in family processes or are directed toward family members. Most people have some awareness of this fact. Indeed, if asked why some individuals commit crimes, the average person is likely to provide an explanation that focuses on how the deviant individual was parented while growing up. Furthermore, in the last two decades, there

has been an increase in the public's awareness of domestic violence. Most individuals appreciate the fact that spouse and child abuse are a part of everyday life for many families; however, other connections between families and crime are less well understood. Few people are aware, for example, of the various ways in which a person's criminal behavior or involvement with the criminal justice system tends to disrupt the lives of other family members, or of the role that marital partners often play in fostering or deterring their spouse's involvement in crime.

Social scientists have defined the terms *deviant behavior* and *family* in a variety of ways. Although the family is a basic social institution in all societies, its form tends to vary considerably from one culture to another. "The family" is an abstract phrase used to denote an array of forms and practices that serve a common set of social and psychological needs for a group of two or more people who share kinship or affective ties. Given the wide variety of forms, perhaps the simplest and most straightforward approach to studying families is to focus on the two core relationships present in most families: (1) the parent-child relationship and (2) the committed relationship between two adults. The parent-child unit and the adult couple unit are fundamental components of a family, and a particular family may have one or both of these relational units.

Social deviance is any thought, feeling, or behavior that is viewed as objectionable by a group of people because it violates the social norms that the group members share

regarding how a person should behave. The present discussion focuses on acts such as childhood aggression, adolescent delinquency, adult crime, and child and spouse abuse as they relate to family processes. Researchers often refer to persons who engage in such behavior as *antisocial*. Such actions stand in contradistinction to *prosocial* behavior, which takes into account the needs and concerns of others and thereby contributes to the welfare of the group. Antisocial behavior, on the other hand, is selfish, hostile, and disruptive, and it threatens the integrity of the group.

Expressions of antisocial behavior tend to vary by age. Antisocial behavior during the elementary school years tends to consist of actions such as bullying others, lying, refusing to comply with adult requests, showing extreme anger and resentment, deliberately annoying others, and being spiteful and vindictive. Delinquency during adolescence consists of antisocial actions that are illegal, such as initiating physical fights, shoplifting, stealing, setting fires, destroying property, or using illegal drugs. Finally, there is the antisocial behavior displayed during adulthood. This can involve a wide variety of criminal behaviors, such as robbery, burglary, physical assault, fraud, sexual coercion, and domestic violence. Individuals who engage in such acts also often display various deviant behaviors that are antisocial but not illegal. This includes actions such as lying, cheating, sexual promiscuity, substance abuse, and general irresponsibility.

This chapter is concerned with the relationship among the family and child, adolescent, and adult antisocial behavior. The family is a core social institution that exists in all societies. In addition to providing food and shelter to its members, the family is the context within which children learn fundamental social skills and satisfy their affective needs. Family relationships offer children a context for learning moral values, self-control, and to love and trust others. Families also meet the emotional and companionship needs of adults. Although individuals in modern society are influenced by many sources other than the family, family factors account for more variance in the rates of antisocial behavior than any other single variable. Therefore, it is essential to focus on the family when trying to gain a complete understanding of antisocial behavior.

Linking Parenting to Delinquency

One of the most widely accepted findings in criminology and developmental psychology is that childhood conduct problems are a strong predictor of subsequent involvement in antisocial behavior. Results from a variety of longitudinal studies show that children who are aggressive and noncompliant during elementary school are at risk for adolescent delinquency and adult crime (Caspi & Moffitt, 1995; Conger & Simons, 1997; Patterson, Reid, & Dishion, 1992; Sampson & Laub, 1993). These findings indicate that antisocial tendencies tend to become manifest during childhood. The roots of an adult antisocial lifestyle

appear to be planted during the person's formative years. Parents are generally seen as the primary agents of socialization in the early years of a child's life. Although inborn traits involving temperament and personality are considered to be important, most social scientists assume that a child's psychological and behavioral development is heavily influenced by the family environment provided by the parents.

Sociologists, psychologists, and criminologists have completed scores of studies that examined the relationship between parental behavior and delinquency. Various parenting behaviors, including parental warmth, monitoring, and consistent discipline, were all found to be inversely related to the chances that a child would become delinquent (L. G. Simons & Conger, 2007). A guiding framework for much of this work was the parenting typology developed by Maccoby and Martin (1983).

Maccoby and Martin's (1983) typology is based in large part on the work of Diana Baumrind (1971) and is organized around two dimensions of parenting: (1) responsiveness and (2) demandingness. *Responsiveness* involves the extent to which parents are approachable, warm, supportive, and attuned to the needs of the child. *Demandingness* refers to the extent to which the parents exercise control over the child through supervision, disciplinary efforts, and a willingness to consistently impose consequences for violations of expected behaviors. These two dimensions of parenting can be used to generate a typology of four parenting styles. *Permissive* parents are high on responsiveness but low on demandingness, whereas *authoritarian* parents are low on responsiveness but high on demandingness. *Neglectful/rejecting* parents are low on both responsiveness and demandingness. Finally, *authoritative* parents are high on both responsiveness and demandingness. Baumrind asserted that the best approach to parenting is the style displayed by authoritative parents. In other words, children need support and nurturance combined with structure and control. Consistent with this contention, three decades of research has shown that authoritative parenting is positively related to school achievement, psychological well-being, and social adjustment and negatively related to conduct problems and delinquency. Further evidence regarding the importance of parenting was provided by longitudinal studies showing that aggression and conduct problems during childhood predicted adolescent delinquency and adult crime. This suggests that exposure to inept parenting during childhood may set the stage for a deviant life course trajectory.

One of the early criminological theories that included the parent-child relationship as part of an explanation for deviant behavior was Travis Hirschi's (1969) *social control theory*. Although many researchers felt this theory began to address the importance of parental behavior in explaining child conduct problems, studies indicated that something more than the parent-child bond, as suggested by social control theory, explained this link. Later, *self-control theory* was proposed. In *A General Theory of Crime*, Gottfredson

and Hirschi (1990) argued that it is persons low in self-control who are attracted to crime. They described individuals low in self-control as impulsive, uncompromising, self-centered, insensitive, prone to risk taking, and unconcerned about long-term consequences. Such persons are attracted to crime, which provides immediate gratification, whereas they avoid activities that involve a lot of time, energy, and delayed gratification. According to Gottfredson and Hirschi, adolescent delinquents and adult criminals are lazy, lacking in self-discipline, and looking for the easy way to get what they want.

Gottfredson and Hirschi (1990) argued that we all enter the world low in self-control. Infants and toddlers, for example, are impulsive and self-centered, and they want immediate gratification. With time, however, most individuals learn to delay gratification. Instead of giving in to their desire for immediate reward, they exercise self-control and act in a manner that takes into account the consequences of their actions for themselves and others. This being the case, where does this self-control come from? Gottfredson and Hirschi asserted that the answer involves parenting. In addition to being caring and supportive, the child's primary caregiver must set behavior standards, monitor the child's behavior, and be willing to discipline the child when the standards are not met. When caretakers do this in a consistent fashion, the child learns self-control. On the other hand, children fail to develop self-control if they are raised by caretakers who are lax in nurturance, monitoring, and discipline.

Overall, evidence from various studies suggests that self-control explains only a portion of the relationship between parenting and antisocial behavior. The available evidence suggests that the story of crime is more complicated than that suggested by Gottfredson and Hirschi (1990). Whereas social control theory emphasizes the impact of parental behavior on children, social learning theory focuses on the reciprocal or mutual influences that exist between parents and children, and it stresses the importance of peer effects as well as the manner in which parents influence their children's friendship choices. Perhaps the best example of research based on this perspective has been conducted by Gerald Patterson (e.g., Patterson, 1982). Over the past several years, Patterson and his colleagues have pursued longitudinal studies concerned with the manner in which family and peer processes combine to produce child and adolescent conduct problems. The findings from this program of research provide support for their *coercion model* of antisocial behavior, which posits that delinquency and crime develop in the following fashion.

The process begins with an irritable, explosive parent. Regardless of the reasons for such a disposition, such individuals tend to engage in negative scanning of their child's behavior so that even neutral actions evoke criticism and denigration. These verbal assaults often produce an angry, defiant response from the child, who feels unfairly attacked and mistreated. The result is an escalating spiral of aversive

exchanges that operate to reinforce the child's antisocial behavior and the parent's inept parenting. It is important to note that in families with antisocial children, at least half of the time these escalating aversive exchanges terminate with the parent capitulating. The parent engages in verbal remonstrations and threats but little or no actual follow-through. The child responds defiantly, and the parent eventually backs down. Using the principles of social learning theory, the parent gives in to the child, thereby positively reinforcing the child's oppositional and defiant behavior. The child learns that if he is nasty enough, he will get his way. Also, negative reinforcement is operating as the child's aggressive behavior neutralizes or deflects the unpleasant intrusions of the parent. The child behaves aggressively, and the parent discontinues his or her criticism and threats.

Concomitantly, the parent is negatively reinforced for giving in to the child. Usually, once the parent backs down the child's behavior improves, and his aggressive posturing gives way to a more pleasant demeanor. In addition, the parent experiences punishment when he or she tries to discipline the child. Any attempt to correct the child elicits a very unpleasant response from the child. Therefore, the interaction taking place within such families trains parents to be inconsistent and to back down while training children to use aggressive actions to coerce others into giving them their way. Instead of learning prosocial, problem-solving behaviors that involve sharing and compromising, these children learn to use anger and defiance as a way of solving problems and getting what they want from others.

This interpersonal style tends to be generalized to interactions with peers. The coercive child insists on having his or her way; refuses to compromise; and uses angry, aggressive behavior to bully others into complying with his or her wishes. Much of the time, this behavior is rewarded, because conventional children often give into this display of belligerence and hostility. Thus, interaction with peers tends to reinforce the aversive interpersonal style that the child learned at home. Although the behavior of the antisocial child often leads to immediate or short-term rewards, the long-term effect is usually quite different. Conventional youth do not want to play with someone who uses aggression and defiance to get his or her way. Thus, the long-term consequence of the antisocial child's aversive behavior is rejection by conventional peers. What such children fail to recognize, however, is the manner in which their own coercive style of interaction contributes to their interpersonal and academic difficulties.

By default, these socially rejected youth establish friendships with each other, forming a deviant peer group. It is important to note here that affiliation with deviant peers is the primary avenue whereby a child's coercive interpersonal style escalates to delinquent and criminal behavior. The deviant peer group provides a context for experimenting with various deviant behaviors. It serves as a training ground for shoplifting, drug use, fighting, and the like. Association with other deviant youngsters provides antisocial youth with attitudes, motivations, and

rationalizations that support involvement in a wide variety of illegal activities.

The coercion model does not address the way parents influence a child's selection of a peer group. There is rather strong evidence that parental behavior influences a child's friendship choices. Past research indicates that parents often use a variety of strategies to structure their children's peer affiliations: They encourage their children to join one group over another; they select the schools that their children attend; and they promote participation in various conventional activities, such as organized sports and other extracurricular activities at school. Such efforts reduce the probability that a child will affiliate with deviant peers.

The Corporal Punishment Controversy

As described earlier, several contemporary theories of deviant behavior agree that effective parenting behaviors decrease the probability of delinquent behavior. In recent years, some researchers have argued that there is convincing evidence for another generalization regarding the effect of parental behavior on child conduct problems. They contend that research has confirmed that children subjected to corporal punishment are at risk for delinquent and criminal behavior. Physical discipline has this effect, they argue, because parents who engage in this behavior inadvertently teach their children that aggression and coercion are legitimate approaches to solving problems, and corporal punishment fosters anger and generates opposition and defiance. Thus, instead of deterring misbehavior, it operates to amplify a child's antisocial tendencies. These researchers consider exposure to corporal punishment during childhood to be a major cause of adolescent delinquency and adult crime and aggression. On the basis of arguments such as these, the American Academy of Pediatrics and the American Psychological Association have taken firm stances against the use of any corporal punishment. Some people believe that scientific support for this position is so strong that Congress should follow the example of several European countries and pass legislation prohibiting adults from using corporal methods to discipline children. Currently, parents are forbidden to use corporal punishment as a form of discipline in Austria, Cyprus, Denmark, Finland, Germany, Italy, Latvia, Norway, and Sweden.

The majority of American parents sometimes use corporal punishment to discipline their children. One investigation found, for example, that over 90% of American parents have spanked their children by the time they are 3 or 4 years of age (Straus & Gelles, 1986). The effects of corporal punishment are an empirical question. Moral objections are a separate issue. This chapter focuses on research findings and lets readers draw their own conclusions regarding the ethics of physical forms of punishment.

It is important to distinguish spanking from harsh physical punishment. In 1996, a conference of developmental psychologists defined *spanking* as an approach to physical

discipline that is noninjurious and is administered with an opened hand to the extremities or buttocks. At most, such punishment inflicts only a minor, temporary level of physical pain. More severe forms of corporal punishment involving slapping, kicking, shoving, and hitting with an object would be considered abusive.

Research indicates that modeling often results in discriminative learning whereby we learn to recognize (or discriminate) between the circumstances under which an action is or is not appropriate. Consider the example of a parent who uses low-impact spanking (i.e., a swat to the buttocks using an open hand) as a last-resort punishment when her preschooler misbehaves, but never uses corporal punishment with her older children and frequently talks about the importance of people not being violent or aggressive with one another. Also, when she administers a swat to her preschooler, she explains the importance of the rule that her child violated and indicates that little children get spanked when they defy their parents' guidance. In this case, the child might be expected to learn that it is legitimate for parents to sometimes spank a misbehaving preschooler whereas in general people should not hit each other.

Children often respond with anger, aggression, and defiance when they perceive that they have been treated unjustly. Past research shows that corporal punishment is most apt to be perceived as legitimate if it is mild, is used with young children, is administered by a warm and caring parent, and occurs within a cultural context that legitimates corporal punishment. Under such circumstances, physical discipline is apt to operate as a deterrent to child conduct problems. Conversely, physical discipline is likely to elicit perceptions of injustice and mistreatment when it is severe, is directed toward older children, is dispensed by a rejecting parent, or occurs within a cultural context that disapproves of corporal punishment. Under these circumstances, physical discipline is apt to generate belligerence, defiance, and other conduct problems.

Unfortunately, much of the research on corporal punishment usually does not distinguish between the consequences of mild forms of physical punishment and more extreme forms that might be considered abusive. The few studies that have taken severity into account, however, have found that individuals exposed to moderate levels of physical punishment are no more likely to engage in antisocial behavior than those whose parents did not use corporal punishment, whereas persons who experienced severe physical punishment show significantly higher levels of antisocial behavior than those who received either no punishment or moderate corporal punishment. Several studies have reported that physically abused children are at risk for a variety of antisocial behaviors, including delinquency and substance abuse. In general, the association between harsh parenting and antisocial behavior is stronger for children who have experienced more extensive abuse.

The effects of physical discipline are likely to differ by age of child. Although moderate spanking may be a deterrent for preschoolers, corporal punishment might be

expected to escalate the deviant behavior of older children and teens. Past research provides support for this observation. Clinical studies with preschoolers or kindergarteners have found that spanking increases compliance, as well as the effectiveness of time-outs and reasoning, whereas those that focus on parental behavior during late childhood or early adolescence tend to find a positive relationship between spanking and antisocial behavior.

A child's reaction to physical punishment may depend, at least in part, on the quality of the relationship that she has with the caregiver. Warm and supportive parents may be able to use corporal punishment to obtain child compliance. On the other hand, corporal punishment may foster defiance and aggression when it is administered by cold, harsh, or uninvolved parents. Although few studies have addressed this issue, the evidence suggests that corporal punishment tends to escalate child behavior problems when it takes place within the context of a troubled parent-child relationship. These negative effects are much less likely to occur when physical discipline occurs within a warm and nurturing family environment.

There are also differences in the effects of corporal punishment by ethnicity. Several studies have reported that physical discipline is more widely used and accepted by African American parents than by European American parents. Furthermore, research shows that European American children often view physical discipline as an expression of parental hostility and disregard, whereas African American children tend to accept such discipline as a valid expression of parental concern. Several studies indicate that African American children show less aggression and defiance, and more compliance, in response to physical punishment than European American children. It appears that corporal punishment tends not to have negative consequences when the family is part of a culture that legitimates such parenting practices.

In summary, physical discipline is apt to foster compliance and be perceived as legitimate when (a) it is mild (e.g., a spank to the buttocks with an open hand); (b) is administered by a caring, supportive parent; and (c) the child is between 2 and 6 years of age. In contrast, physical discipline is likely to foster defiance and aggression when (a) it is severe; (b) is administered by a harsh, rejecting parent; and (c) the child is a preadolescent or teen. However, the decision to use physical punishments to discipline children involves more than the question of efficacy; it is also an ethical matter. Whereas social scientists can address the question of effectiveness, it is beyond the scope of science to draw moral conclusions. Ultimately, each individual must determine the circumstances, if any, under which it might be appropriate to use physical discipline.

Family Structure and Delinquency

There has been a substantial increase in many types of adolescent problems since the mid-1960s. The rates of adolescent

crime, substance abuse, suicide, school dropout, and teen pregnancy, for example, all have shown dramatic growth during this period. Some scholars have noted that the rise in child and adolescent problems parallels the increase in divorce, cohabitation, and births to never-married mothers that has occurred in recent decades. Indeed, several studies have reported strong associations between the proportion of female-headed households and adolescent and adult antisocial behavior. In most of these studies the effect of family structure is as strong as or stronger than variables such as poverty or race. Research conducted by Rob Sampson (1986), for example, found that rates of violent victimization are two to three times higher among residents of neighborhoods with high levels of family disruption.

Although family structure is a risk factor for child behavior problems, it is also true that there is great variability in outcomes among children from single-parent families and stepfamilies. The evidence indicates that the majority of these children do not manifest behavior problems. In fact, the rates for such behavior problems increase from 5% among children from intact, nuclear families to 10% to 15% of children from single-parent or divorced families (Hetherington & Stanley-Hagan, 1999, R. L. Simons & Associates, 1996). The vast majority of children from a single-parent family or stepfamily do not develop conduct problems; hence, such an expectation would turn out to be erroneous more often than not. Accurate prediction of which individuals are most vulnerable to a particular risk factor usually requires knowledge of the mechanisms by which the condition produces its deleterious effects. Thus, if we are to identify children from single-parent and stepparent families most at risk for adjustment problems, we need information regarding the manner in which family structure increases a child's odds for developmental difficulties. Research indicates that in large measure, family stress and disrupted parenting explain which children are likely to manifest conduct problems (Amato, 2000).

Given that diverse family forms are an inevitable feature of American society, there is some controversy associated with conducting research on the consequences of variations in family structure. The findings of such research are often used by political groups that are opposed to diversity and gender equality. Also, most parents who divorce undoubtedly do so as a last resort, and the welfare of their children is of great concern to them. Some people have suggested that to do research on these families that highlights their problems may seem cruel in light of the other difficulties they face. Although these issues are important, social science is concerned with describing and explaining empirical reality. Hence, it is essential that we as scientists do our best to avoid denying or distorting facts because of personal values or ideology. Such a commitment is not only in the best interest of science but also is the approach most likely to benefit society. Research has clearly established a link between family structure and an elevated risk for developmental problems. This effect is quite modest, however, and appears to be

largely explained by the fact that the stresses associated with single parents, divorced parents, and stepfamilies tend to compromise the quality of parenting that children receive.

The Effect of Poverty and Neighborhood Conditions

Although the family may be the primary agent of socialization for children, it does not exist in a vacuum. Families are embedded in a broader social environment that can operate to either enhance or undermine parental effectiveness. A family's ability to effectively perform its socialization function is strongly affected by the social context in which it is embedded. This context consists of social institutions such as the economy, the polity, the church, and the neighborhood or community. The values, policies, and integrity of these social systems necessarily influence the functioning and efficacy of families.

Unfortunately, there is strong evidence that children who grow up in poor families are at increased risk for a variety of negative developmental outcomes, including conduct problems and delinquency. Past research indicates that poverty tends to have a disruptive effect on quality of parenting, and this is one of the major reasons that poverty increases a child's chances of deviant behavior. Several studies have reported that economically stressed parents provide less support and monitoring and higher levels of inconsistent and harsh discipline than parents who are more affluent (Brody et al., 2001; Conger et al., 1992; R. L. Simons & Associates, 1996). There appear to be several reasons why financial hardship has a deleterious effect on parental behavior.

At least in part, the less effective parenting demonstrated by poor parents is a consequence of their being preoccupied and consumed with the challenges and stresses of everyday life. Given these concerns, they are often minimally involved in the parenting role until serious or flagrant child misbehavior jars them into action. Such transgressions are likely to demand a harsh response, so that the pattern of parenting displayed is inconsistent and explosive.

The psychological distress associated with economic hardship also increases the chances of ineffective parenting. Economic strain is apt to foster an irritable, aggressive psychological state that operates to decrease warmth and increase hostility toward others, including one's children. Finally, depressed parents are more likely than nondistressed parents to be dissatisfied with social relationships, including the relationships with their children. Several studies have reported, for example, that depressed mothers tend to perceive their children as difficult, and parents are more likely to engage in harsh or punitive parenting when they perceive their children as difficult.

Thus, past research suggests several ways in which the preoccupation and psychological distress that accompany financial hardship tend to decrease warmth and monitoring while increasing inconsistency and hostility. As mentioned

in previous sections, this approach to parenting places a child at risk for conduct problems and delinquent behavior.

Linking Childhood Delinquency and Adult Crime

Research indicates that antisocial behavior in children is one of the best predictors of antisocial behavior in adults. Children who are aggressive and noncompliant during elementary school are at risk for adolescent delinquency and adult crime. This finding indicates that the roots of an adult antisocial lifestyle appear to be planted during the person's formative years. It is extremely rare that a person who was a model child and adolescent suddenly begins to engage in criminal behavior as an adult. Of course, the relationship between childhood conduct problems and adult antisocial behavior is far from perfect: Many delinquent children grow up to be conventional adults. So, what accounts for the link between past and future offending?

The criminological literature contains two very different views of antisocial behavior across the life span. Gottfredson and Hirschi's (1990) self-control theory argues that differences in self-control are established by age 10 and remain reasonably stable throughout the life. Caregiver parenting practices and, to a lesser extent, child temperament are seen as the primary determinants of a child's self-control. The theory views variations in levels of self-control as the primary explanation for individual differences in antisocial behavior throughout life.

Sampson and Laub's (1990) life course approach, on the other hand, posits that the stability of antisocial behavior across the life course is a consequence of deviant behavior at early stages of development that undermines relationships and activities that are important sources of control during later stages. In addition to describing the causal process that accounts for the continuity of antisocial behavior, life course theory identifies events and circumstances that serve as the turning points, enabling individuals with a history of antisocial behavior to adopt more conventional lifestyles. In other words, life course criminologists are concerned with explaining both stability and change in antisocial behavior.

According to Sampson and Laub (1990), childhood conduct problems increase the chances of delinquency during adolescence because they reduce ties to parents, conventional peers, and school. More specifically, in response to childhood opposition and defiance, parents often reduce their efforts to monitor and discipline. A noncompliant attitude also increases the chances that a child will experience academic failure. Finally, conventional peers tend to reject difficult children, increasing the probability that they will drift into a deviant peer group. Unencumbered by parental controls, disinterested in school, and under the influence of a deviant peer group, these antisocial youngsters graduate from oppositional/defiant behavior to more serious delinquent acts. Childhood antisocial behavior

leads to delinquency because of its disruptive effect on parents, school commitment, and peer affiliations.

Life course theory also notes, however, that numerous children who exhibit this sort of problem behavior do not follow this pattern. In fact, longitudinal research shows that the majority of antisocial children go on to lead conventional lives. For example, past research shows that somewhere between 15% and 20% of 10-year-old boys are oppositional and defiant. They are aggressive, impulsive, self-centered, and noncompliant; tend to be rejected by their conventional peers; and represent a challenge to their parents and teachers. By age 18, a small proportion of the cohort, roughly 10%, is severely delinquent. They engage in fights, truancy, robbery, drug sales, and the like. Finally, a somewhat smaller proportion of the cohort, perhaps 5%, is involved in serious crime at age 26. Their criminal activities include a wide variety of illegal acts, such as robbery, burglary, drug trafficking, gambling, and prostitution. Nearly all adult criminals were seriously delinquent during adolescence, and virtually all of the seriously delinquent adolescents were oppositional/defiant at age 10. This does not mean that all antisocial children grow up to be criminals. Only about half of all children with conduct disorder go on to engage in serious delinquency during adolescence, and only about half of all seriously delinquent adolescents engage in criminal behavior as adults. Thus, although childhood deviance increases the chances of adult antisocial behavior, many individuals age out of their antisocial tendencies and adopt a more conventional way of life.

The finding that many antisocial individuals embrace a conventional lifestyle with the passage of time is contrary to self-control theory's contention that by age 10, the window of opportunity for socialization is slammed shut, with those who have not acquired self-control being doomed to a life of delinquency and crime (Burt, Simons, & Simons, 2006). The evidence suggests instead that antisocial behavior shows both continuity and change: Some individuals manifest antisocial behavior throughout their lives, whereas others change and adopt a more conventional lifestyle. There is evidence that children who were highly oppositional but who subsequently experience improved parenting, increased school commitment, or reduced involvement with deviant peers show no more conduct problems during adolescence than boys who displayed little oppositional behavior during childhood. Furthermore, studies have found that job satisfaction and a committed, happy romantic relationship and other family ties mediated a significant proportion of the relationship between adolescent delinquency and adult crime (Simons & Conger, 2007). Thus, troubled adolescents who are able to achieve these successes are more likely to adopt a conventional lifestyle in adulthood, whereas those who fail to do so are more likely to continue on their troubled path toward adult criminal behavior.

Thus, recent longitudinal research tends to support the life course perspective over self-control theory. These studies explain why some individuals manifest antisocial behavior throughout their lives, whereas others desist and adopt a more conventional lifestyle. Studies generally have found

that low commitment to conventional social activities and relationships explains much of the relationship between childhood measures of self-control and future deviant behavior. These investigations also show that antisocial individuals who buck the odds and develop strong commitments to such activities and relationships tend to discontinue their deviant lifestyles. These findings are consistent with the life course perspective but contradict self-control theory.

Marital Violence

The first national survey of family violence was conducted by Murray Straus and his colleagues (Straus, 1974). Sixteen percent of married couples reported a violent incident in the preceding year, and 30% reported at least one incident at some point during the course of the marriage. Slightly more than 6% indicated that there had been an incident of severe violence. To the surprise of almost everyone, the data indicated that wives hit their husbands slightly more often than husbands hit their wives. This pattern has since been corroborated by many studies.

Although this is interesting, it should not be taken as an indication that husband abuse is a serious social problem comparable to wife abuse. This female-to-male pattern is typically confined to fairly minor acts of violence, such as slapping or shoving, and it is unlikely to involve injury. Police records, emergency room data, and criminal victimization surveys indicate that women are far more likely to sustain serious injury at the hands of men. Eighty percent of the partner assaults reported to the National Crime Victimization Survey involved men attacking women (Felson, 2002). Men and women vary tremendously in terms of size and strength, ability to deliver forceful blows, and capacity to defend or escape. Studies that have examined injury rather than just number of incidents conclude that men are much more violent toward their partners than women are.

Researchers have made distinctions between two types of intimate partner violence (Johnson & Ferraro, 2000). The first type, called *common couple violence*, occurs infrequently, does not escalate over time, and rarely results in physical injury or psychological trauma. This is not the type of violence that most human service workers, policymakers, or everyday citizens have in mind when they refer to *spouse abuse* or *battering*. Instead, it is the phenomenon called *intimate terrorism* that concerns society. This type of violence is frequent, persistent, and severe, and it results in physical injury and emotional trauma. It is in response to this social problem that people have established shelters, strengthened restraining orders, instituted mandatory arrest policies, and implemented treatment programs. This assaultive behavior is relatively rare and is usually committed by a man against a woman.

Past research indicates that two types of men tend to engage in intimate terrorism. The first group consists of men who engage in a wide variety of antisocial behaviors besides spouse abuse. For these individuals, severe partner

abuse is an expression of a more general antisocial orientation. Their antisocial behavior appears to be, in large measure, a consequence of having grown up in a disorganized, violent family. In contrast, the second category of batterers displays the characteristics of borderline personality disorder and engages in little antisocial behavior outside of the couple relationship. Their intimate violence appears to be an expression of fear and anger regarding rejection instead of a component of a more general antisocial orientation. Some evidence suggests that these abusers often have grown up in a family characterized by emotional and physical abuse. Apparently, the parents of these individuals set rules and engage in the consistent discipline necessary to otherwise produce a basically conventional lifestyle. The rejection and abuse, however, result in a violent, turbulent approach to intimate relationships.

There is still much to be learned about the types of men who engage in severe partner abuse and the childhood factors that give rise to such behavior. Given the low base rate of intimate terrorism, it is difficult to generate samples of participants. As a result, most studies have focused on common couple violence. Thus, we know much more about minor acts of partner violence than we do about more extreme forms of assault.

Child Maltreatment

Past research has established that there is a tendency for adults to repeat the abuse they experienced as a child (Heyman & Slep, 2002). This phenomenon is often labeled “the cycle of violence.” Although most victims of childhood abuse do not go on to abuse their offspring, they are 10 to 15 times more likely to be abusive parents than persons who were not exposed to abusive parenting. The most popular explanation for this finding involves the idea of *modeling*, from social learning theory. It is assumed that children observe the behavior of their parents and consider it to be normal or typical parental behavior. Later, when they achieve adulthood, they are likely to use these parenting scripts in a reflexive, rather unthinking fashion when parenting their own children.

Recently, some scholars have argued, largely on the basis of work by criminologists, for an alternative explanation for the cycle of violence phenomenon. These researchers argue that abusive parenting fosters a general antisocial orientation instead of simply teaching a dysfunctional approach to parenting. Abusive parenting is seen as increasing the chances that a person will grow up to engage in a wide variety of criminal and deviant behaviors, including harsh and abusive parenting practices. Furthermore, there is evidence that males who were the victims of harsh parenting practices have an increased risk of perpetrating intimate partner violence and sexual coercion (L. G. Simons, Burt, & Simons, 2008).

These two points of view suggest very different images of the abusive parent. The modeling perspective portrays perpetrators as ordinary citizens, conventional in all respects

except for their abusive behavior. Scholars who support the antisocial orientation point of view, on the other hand, argue that most abusive parents are far from being ordinary; instead, parents who engage in extreme abusive practices are likely to have a history of involvement in a wide variety of criminal and deviant behaviors as well. We will have to wait for future research to establish which viewpoint is more correct.

Conclusion

Although this chapter has focused on a wide range of topics, it has provided clear and consistent support for a simple but important thesis: Exposure to inept parenting practices increases an individual’s risk for childhood conduct problems; adolescent delinquency; and adult antisocial behavior, including marital violence and child abuse. However, factors such as educational success, a conventional friendship network, a happy marriage, and a satisfying job can operate to moderate this risk. Unfortunately, individuals exposed to inept parenting often possess antisocial characteristics that reduce their probability of acquiring or gaining access to these moderators.

The theories and studies discussed in this chapter all suggest that inept parenting increases the chances of child conduct problems, adolescent delinquency, and adult crime; however, it is important to not overstate the case. On the one hand, it is true that the roots of an adult antisocial lifestyle appear to be planted during a person’s formative years, and parenting has much to do with the formation of these roots. The evidence reviewed in this chapter indicates that it is extremely rare that a person who was a model child and adolescent suddenly begins to engage in criminal behavior as an adult. On the other hand, the relationship between childhood conduct problems and adult antisocial behavior is far from perfect—indeed, the majority of delinquent children grow up to be conventional adults!

It is also important to remember that other factors besides parenting have been shown to influence involvement in delinquent and criminal behavior. Factors such as lack of occupational opportunity, living in a disadvantaged neighborhood, stressful events, and racial discrimination are associated with crime and delinquency. If society is to address the problems of crime and delinquency, it must pursue policies that address the full range of factors that influence participation in such behavior. It is important that social scientists and policymakers not overlook the family. Indeed, the effects of many of the social factors just mentioned may be mediated by family processes. Family religiosity, for example, appears to reduce delinquency, at least in part, because religious parents tend to engage in high levels of monitoring and consistent discipline. Also, there is evidence that part of the association between community disadvantage and delinquency is explained by the disruptive effect that such community conditions have on parental behavior. In the past, criminologists and sociologists have

often ignored findings regarding a link between parenting and delinquency, treating such findings as narrow and socially conservative. Research results are not socially conservative, however, if they lead to social change.

It is important that social scientists and policymakers think systematically about steps that might be taken to enhance the quality of care provided to children, especially during the formative years. Unlike criminological theories concerned with economic and community factors, theories of deviant behavior that focus on family processes are often seen as having few policy implications. This is simply not the case. It is probably no more difficult to formulate policies that enhance quality of parenting and child care than it is to design policies that increase access to jobs or reduce poverty and discrimination. Instead of simply blaming parents for not doing a better job of raising their children, society needs to pursue social policies that strengthen families and enhance the quality of child care.

GENDER AND CRIME

JANET T. DAVIDSON

Chaminade University of Honolulu

MEDA CHESNEY-LIND

University of Hawaii

The study of the nature and extent of crime has largely been the study of the nature and extent of male crime. The results of largely male-based studies have been used to craft programs, interventions, and punishments that would be applied to all offenders. These male-based interventions have historically been merely used to respond to girls' and women's crime on the basis of the assumption that a one-size-fits-all model of crime, punishment, theory, and intervention works for both genders. Researchers in the 20th and 21st centuries, though, have challenged the notion that female offenders are the same as male offenders, that the two commit crimes for the same reasons and should be treated in exactly the same manner by the criminal justice system.

The subject of gender and crime is complex, multifaceted, and certainly worthy of serious scholarly attention. For the sake of cohesiveness and general education, this chapter focuses on women and crime; specifically, it outlines the historical lack of specific focus on female criminality and the complications this paucity of attention has thus created for female offenders. Attention is paid to important theoretical perspectives informing the field of gender and crime; female pathways to crime; recent trends in female criminality; and, finally, women's experience of the criminal justice system, including important trends in the imprisonment of girls and women.

Male-Based Criminology and Explanations of Female Criminality

As this chapter is being written, we can say that a lot is known about the nature and extent of criminal offending. The earliest thinking about crime came from religious leaders and philosophers; often, these perspectives speculated on both the origins and morality of criminal acts as well as the proper sort of responses to these offenses. The first true empirical studies of criminal offending were conducted by Cesare Lombroso, who believed that there was an important link between biological factors and crime causation. In other words, it was believed that certain offenders were born criminal and could be identified by certain biological defects, such as high cheekbones, baldness, and shifty eyes. Scholarship on the nature and extent of crime has moved far beyond these appearance-based biological factors. Contemporary thinking about crime causation is much more complex and often involves a mix of sociological or psychological factors.

Regardless of the scope of the theoretical perspective taken or the variables included, criminology has historically been a field dominated by male scholars seeking to explain the criminality of other men. Girls and women who committed crimes were for too long the forgotten offenders. Indeed, the term *the invisible offender* is often used by feminist scholars to describe the lack of scholarship on and

knowledge of female offenders. Women were either eliminated from samples or data on them were excluded from analyses seeking to explain crime or understand the effectiveness of the criminal justice system. The result of this andocentric focus is that theories of crime and justice were really theories of male crime and justice. The specific focus on female offenders began in the 1970s largely because of the work of feminist scholars. Indeed, the number of scholars labeled *feminist criminologists* has continuously increased during this time span and has resulted in a widening of the research agenda for scholars exploring the topic of gender and crime. Prior to this era, research on girls or women and crime tended to be haunted by stereotypes about “evil” and “bad” women, and the work focused almost exclusively on prostitution. Feminist scholars, by contrast, began to explore whether girls and women committed crime for different reasons than boys and men; they also focused on a wider range of offenses. Thus, part of feminist scholarship in this area was and is to question criminological knowledge that was male based and male informed as well as to build a new criminology with female offenders squarely as the center of inquiry. Feminist scholars also began an exploration of girls’ and women’s experiences in the criminal justice system, most specifically, the experience of women in prison.

From the beginning, feminist criminologists addressed the paucity of research and theory regarding female offending. They also called attention to the fact that men, too, have a gender, and thus they propelled a new line of research—masculinities research, which explores the role played by masculine expectations in certain forms of male crime. Although the term *feminism* often evokes negative connotations in the lay population, feminist scholarship in criminology foregrounds gender; that is, feminist criminologists do not assume that the factors that are significant in explaining male criminal behavior will necessarily also predict female crime. Feminist scholarship also assumes that gender is constructed and is shaped by history, culture, and the sociopolitical climate. One’s gender often enhances or limits opportunities and social participation in very important ways, and these systems of male privilege and the ways in which they interface with the policing of women are also important to feminist criminologists.

Some of the more salient aspects of gender, relative to crime and the criminal justice system, highlighted by feminist research include the notion that girls and women in the criminal justice system are more likely than boys to have histories of sexual and physical victimization; that women in the criminal justice system are frequently sole caregivers of dependent children; and, finally, that the abuse that characterized their childhoods continues on into adulthood. Along with these differences, criminalized girls and women share with their male counterparts certain attributes: Girls and women who commit crimes are likely to come from economically marginalized communities,

many have very spotty employment histories, and many of the girls and women in prison are members of racial minority groups. Important as these insights are, there is no single feminist approach; instead, feminist criminology, as a part of feminist theory, has been informed by a variety of feminist perspectives.

Some scholars have approached the study of girls, women, and crime from the liberal feminist perspective. This perspective views the disadvantage, as well as other social problems, faced by women as a direct result of a society that views women as unequal to men and believes that, if discrimination against women is the problem, then laws mandating equal treatment on the basis of sex are the solution. Scholars adopting this tradition often point to the myriad examples of women and men being treated in unequal ways by the criminal justice system, such as the failure to allow women on juries until the middle of the 20th century and the difficulties that women experienced getting admitted to law schools during most of the 20th century. Advocates of the liberal view use education, integration, and litigation to address gender inequality.

Radical feminists see an existing social system, especially one rooted in patriarchy (institutional arrangements that enforce male privilege), as crucial to understanding women’s status (and women’s crime). Radical feminists thus move beyond simply using the social structure as an explanatory framework and directly challenge the existing system as one way to equalize men’s and women’s power and status within society and thus elevate the overall status of all women. Scholars adopting this perspective have been responsible for informing the nature and extent of female victimization (in particular, wife battery and sexual assault) at the hands of males, often in intimate and power-imbalanced relationships.

Marxist scholars view capitalistic systems as particularly problematic for societies in general. The unequal class relations, whereby individuals in the upper classes have the power to control those in the lower classes (e.g., through wages and access to lawmaking and other power establishments), prove problematic in myriad ways for people without power. Clearly, this perspective focuses on the crimes of the powerful, which are often not prosecuted, while the crimes of the powerless are hyped and heavily policed. In line with this view, Marxist feminists observe capitalism as the most important social structure, one that places women at a societal disadvantage over men because they are even more economically marginalized than their male counterparts.

Socialist feminists point out that two of the most important social structural conditions, capitalism and patriarchy, place women at disadvantage. Thus, these scholars tend to take a more holistic view of how women are situated in society in terms of power and status. At an aggregate level, women in general occupy lower power and status relative to men; thus, socialist feminists see the disadvantages

faced by women as a direct result of this placement. From this perspective, society would need to be completely restructured away from both capitalism and patriarchy to alleviate both gender and class inequities.

Third-wave feminists focus on how gender, race, and class intersect to put some women at greater disadvantage than others. For many feminist scholars this perspective marked an important improvement over others, because the prior implication had been that all women were situated equally within society. Third-wave feminists, however, have made the important point that salient distinctions should be noted in class and ethnic differences. In other words, although women, relative to men, are placed at a disadvantage, not all women are equally placed and valued within society. Gender certainly has a significant impact on a person's placement within the social, class, and power systems of a society, but so do race, ethnicity, and class.

It is important to note that the study of masculinities also emerged as feminists focused on the role that gender plays in crime causation. Through the study of gender, crime, and victimization, feminist scholars refocused attention on male offenders and the role played by male gender expectations in crime. Again, much of criminological thought has taken for granted that criminal behavior is simply male criminal behavior. Few ever questioned how specifically male or female socialization lead to participation in crime and violence. Again, it is important to note that although there is no one feminist theory, all of these feminist-based theories have gender, typically the female gender, as the overriding concern central to their scholarly inquiry. Within criminology and criminal justice, these feminist theories specifically consider the disadvantages that girls and women face in society and how these relate to victimization and to criminal careers. Finally, these theoretical perspectives often offer suggestions to improve the plight of girls and women in society so as to reduce their need to engage in criminal conduct.

Drawing from these and other important feminist perspectives, gender-specific explanations of female criminality include both theoretical frameworks within which to understand offending behavior as well as ideas for change that stem from these perspectives. Feminist criminologists have remained concerned with questions of whether, in fact, male-based theories of crime apply to explanations of female criminality; why gender matters so much in official measures of crime; why women are victimized at much higher rates than men; how and whether women are treated differently within the criminal justice system; and why women appear over- and underrepresented relative to men in certain crimes. This is certainly not an exclusive list, but it creates a streamlined method of summarizing the primary concerns of the majority of feminist criminological work to date.

The feminist focus on women arguably began with a focus on women's victimization in a largely patriarchal system. The focus on female victimization inevitably led to the discovery of an important link between girls' and women's victimization

and their later histories of offending. Furthermore, this focused inquiry on female offending highlighted the lack of much-needed scholarly attention to women's crime. Specifically, feminists have been concerned with how a gender-based social structure (i.e., one dominated by patriarchy) has influenced women's social participation in ways that disadvantage them. In this realm, gender is accepted as something socially constructed and different than biological sex. Gender—masculinity or femininity—is imbued with deeply embedded social meanings and expectations.

Indeed, it is important to note that feminist scholarship, regardless of its form, has helped transcend the dichotomy between crime as male and victimization as female. Indeed, feminist scholarship has refocused attention on men and crime and what “doing gender” means for both. Unfortunately, the lack of research and other scholarly attention to women's crime has yielded consequences. First, scholars, instead of attempting to understand why women commit crime, have labeled women “bad” if they committed crime. Women have historically and unquestionably been treated in overly controlling ways, especially in patriarchal systems that value “good” women, that is, those who are largely subservient to men and to male-created institutions. Second, policies, practices, and programs designed for male offenders have been applied to female offenders in largely unacknowledged ways. The number of women as arrestees and as members of correctional populations has gone largely unnoticed or studied, even when their numbers have grown at rates faster than men. Contemporary scholarship has moved beyond the invisibility of female offenders, though. The rest of this chapter outlines what we know about women's pathways into crime; their patterns of victimization; the nature and extent of female offending; and their participation in the criminal justice system, including their experiences in jail and prison.

Pathways and Women's Crime

For many people, the pathway to crime is complicated, and for women this picture is no different. Women do tend to have patterns in common with men, but there is now a wealth of documented gender-specific factors related to women's participation in crime and in the criminal justice system. Feminist scholarship has, again, helped detail how women's roles in society have traditionally been ignored within the criminal justice system and has helped provide explanations of female offending. Current research documents how the complexity and the context of the female life is often the root of her involvement in offending and in the criminal justice system. In short, women have significantly greater histories of trauma, addiction, relationship difficulties, abuse, and economic marginalization than their male counterparts. A type of life course perspective, called the *pathways perspective*, currently exhibits the best method of understanding women's involvement in offending and in the criminal justice system.

Girls and women suffer rates of victimization and abuse (sexual, physical, and emotional) at much higher levels than their male counterparts. The most recent survey of national correctional populations (including inmates and probationers), for example, demonstrated that well over half of the female jail inmates had ever been physically or sexually abused, compared with fewer than 1 in 5 of the male inmates. Furthermore, females' abuse occurs at disproportionate rates both before and after they enter legal adulthood; in other words, females are more likely to suffer serious abuse as both girls and as women. Existing research supports a link between child and adult victimization and female criminality, and women in the criminal justice system have higher levels of abuse than the general female population. Trauma theorists assert that these past abusive events are often cumulative and result in trauma that is rarely treated in any professional manner. Thus, women adapt to the trauma in ways that are deemed criminal, especially through the use of drugs and other substances and crimes designed to support these addictions.

Women are more likely than men, at an aggregate level, to be incarcerated or otherwise under correctional supervision for drug and property offenses. Another national survey of incarcerated individuals demonstrated that, in 2006, for women, 28.7% were sentenced for a drug offense and 30.9% were sentenced for a property offense, compared with corresponding rates of 18.9% and 20.1% for men. Female offender involvement with drugs and other substances is multifaceted, and property crimes are often drug related. Existing research demonstrates that factors such as trauma, abuse, women's subservient roles in society, health problems, poor self-image and self-efficacy, and relationship difficulties are often directly related to substance use and related to female offending. Addiction theorists posit that we could indeed reduce levels of female offending if we addressed the gender-specific factors that lead to addiction and drug-related crimes.

Other scholars have focused on differences in female-specific relationships and the interaction with individual and social development. Because of differential socialization processes, girls mature into adulthood differently than do boys, and they do so in ways that place them in relatively vulnerable and disadvantageous positions. The prevalent histories of abuse for girls leave them vulnerable to lower levels of self-worth and empowerment and a diminished ability to have meaningful relationships. The role a patriarchal system has in socializing female expectations and responsibilities is beneficial to understanding the gender-specific strains that leave girls and women susceptible to crime and substance use. Furthermore, women are more likely to be raising dependent children alone than are men, and this, coupled with their own difficulties with relationships, can often create a cycle of dysfunction.

The pathways perspective is a particularly robust theoretical explanation for female involvement in crime. This theoretical perspective takes a more holistic stance toward women's involvement in crime by incorporating all of the

gender-related risk factors thought to contribute to female criminality. When the context of female social participation is placed squarely in the context of a patriarchal society, one that limits female participation in meaningful ways and labels females "bad" when they do not follow gender-related rules, the transparency of their life problems and the intersection with crime is noticeable.

A pathways, or *life trajectories*, perspective informs us that girls and women in the criminal justice system suffer higher rates of victimization than boys and men in their families of origin and within their intimate relationships. They are more likely than men to self-medicate with both legal and illegal substances, to have fragmented family histories, to suffer from physical and/or mental health problems, to be unmarried mothers with minor children, and to have limited vocational skills and sporadic work histories. These factors, singularly or, more often, simultaneously, come together in ways that positively affect women's offending and involvement with the criminal justice system.

These factors increase the likelihood of offending and other criminal justice involvement for women, especially for women of color and those with lower socioeconomic status. The socialization of girls and women shapes the available opportunities (perceived or otherwise) for women who find themselves on the fringes of society. These limited choices often lead females, first as girls and later as women, into homelessness, substance use, survival crimes (often as prostitutes or in the sex industry), unhealthy and often abusive relationships, and more serious criminal offenses.

Gender operates in very powerful yet often-unnoticed ways. Girls' and women's lives are limited and shaped by circumstances that devalue them relative to their male counterparts. Although we are more aware of some of these outcomes, such as lower pay for similar work, the manner in which girls and women enter the criminal justice system has remained unfortunately invisible for too long. Note that we are not claiming that feminist scholars do not wish to imply that the prevalent histories of abuse and vulnerable positions within patriarchal societies leaves women without any sense of agency; instead, the point is that females who find themselves represented as offenders and other criminal justice participants are more likely than others in the general population to exhibit the factors mentioned in this section.

The Nature and Extent of Women's Crime

One of the best predictors of crime, especially violent crime, is gender. Males are responsible for a disproportionate amount of reported crime. For example, in 2006, males made up 82.8% of the individuals arrested for violent crimes (murder, aggravated rape, robbery, and aggravated assault) and 68.8% of the individuals arrested for property crimes (burglary, motor vehicle theft, and larceny theft). Women, however, made up 64.2% of the prostitution and

commercialized vice arrests, and girls represented over half of all runaway arrests (refer back to the “Pathways and Women’s Crime” section for explanations of the higher representation of females in these areas).

Although females represent roughly one quarter of all official arrests, their participation in the criminal justice system has grown at a rate faster than men’s. There is no dispute that the overall percentage of arrests accounted for by women has increased. More disputable, though, is what these numbers really mean. It might be that women are indeed committing more crime now than they were even 30 years ago. The recent literature suggests that it is more likely, though, that the level of criminality has not significantly risen but that attention to female behavior has increased, particularly in the area of assault.

Violent crime has historically and consistently remained a largely male phenomenon. This is true despite contemporary media efforts to depict ever-increasing levels of female violence and “bad” girls. Indeed, the percentage of females arrested for homicides has significantly decreased over the past 40 years. Female arrests have increased significantly for property crimes, especially larceny and fraud, as well as for drug offenses. Both of these changes in female criminality are likely a result not only of some increased offending but also of increased attention to these behaviors by law enforcement, at local and federal levels.

As discussed earlier, the women who most often become involved in crime and end up in the criminal justice system tend to be economically marginalized and have a lack of educational and/or vocational opportunities. Women’s economic status, coupled with their more extensive histories of abuse, make it understandable that the crimes they tend to commit more often, or in which they are otherwise over-represented, are ones that could be considered “survival crimes.” For example, property crimes such as larceny or theft; fraud forgery; and sex crimes, such as prostitution, are viable methods of survival for women on the economic margins. If there is an average female offender, she is young, a single mother, and a woman of color; is undereducated and not well skilled; and has a history of abuse. These factors shape the nature and extent of crime for women as compared with men.

In any discussion of women’s criminality it is crucial to understand women’s involvement in drug use. As mentioned earlier, women are more likely to turn to substances, both legal and illegal, as a means of self-medication for untreated emotional trauma, often related to histories of abuse. This has become even more problematic for women as the United States has been imposing tougher sanctions for illegal drug use. As the following sections highlight, women’s faster rate of prison growth is largely attributable to mandatory drug sentencing laws.

It is increasingly difficult and indefensible to render girls and women invisible given their increased participation in the criminal justice system over the past few decades. Their increased presence in official arrest and

conviction records also has implications for the manner in which they should be processed through the criminal justice system and otherwise treated and supervised within the community. The next two sections deal with these important issues.

Women and Equity in the System

The issue of gender equity in the criminal justice system is one that has remained contentious. As stated earlier, the criminal justice system has largely been defined and built around what we know about male offending and has merely been applied to women. Many consider this to be equitable treatment. However, given what is known about female pathways to offending, the “add gender and stir” approach to criminal justice policy is not equitable. Laws, policies, punishment, and programs have mainly been developed with males in mind and are assumed to be good enough for females.

The current manner in which women enter and are treated in the system often leaves them disadvantaged relative to their male counterparts. Equitable treatment for a female offender would likely involve considering her gender-specific needs and crafting a system that would specifically target these areas. These gender-specific factors rarely enter into discussions of criminal or penal policy; thus, the possible negative impact on female offenders is not discussed or analyzed ahead of time.

Women are affected at many different stages in the system. For example, at the time of arrest, women are less likely to be able to post bail, because they typically do not have the same economic resources as male offenders. Women are more likely to be addicted to drugs or using drugs to self-medicate and are thus at greater risk of exposure to mandatory minimum prison sentences. In terms of classification schedules, female offenders tend to be overclassified in security risk levels relative to their male counterparts.

Because women, compared with men, are more likely to have been the primary caregivers of their dependent children, they are also more likely to be affected by the 1997 Adoption and Safe Families Act, which allows for the termination of parental rights if the parent has been consecutively without his or her child for 15 months. Because the average sentence for females is currently greater than 15 months, they are at greater risk than males (who are much less likely to have remained the caregiver of the dependent child) to permanently lose custody of their children.

Supervision strategies in prison and for probation and parole have been crafted with the male offender in mind. Equitable treatment for women would include supervision strategies designed for female offenders and would be cognizant of the histories of abuse that the majority of women in the system demonstrate. Furthermore, the competing demands of many female offenders in the community (child care, lower vocational skills and pay, familial

responsibilities) often translate into a need for greater support if the goal is to improve success while under community supervision.

Many scholars argue that the current criminal justice laws, from which other criminal justice processes certainly flow, involve gender discrimination, even though they appear gender neutral on their face. However, laws may be differentially applied to males and females, or they may punish male victimizers more than female victimizers (e.g., aggravated assaults vs. assaults related to domestic violence). Some laws, such as mandatory arrest in domestic violence cases, have actually created more difficulty for female victims than was intended.

Some scholars have argued that women are in fact treated in a chivalrous fashion and are given lighter punishment than men or that women are treated more harshly than men because they appear to be nonnormative, or they are “evil.” Neither the chivalry nor the evil-woman hypothesis is fully supported by the research. Although there is some evidence for both of these, the weight of the evidence indicates that criminal justice decision makers, from law enforcement through corrections, tend to consider different factors when considering how to treat males versus females.

Regardless, when it comes to differential treatment, the problem is one of translation, or lack thereof. Rarely is the growing and emerging research on female offenders used in meaningful discussions of criminal justice treatment. The existing research clearly demonstrates meaningful qualitative differences in the nature and extent of female offending. Females are represented in certain offender groups more than men and, in the main, commit crimes for different reasons than men (e.g., the pathways perspective). Thus, the contemporary challenge to the system is to find a way to use existing research and knowledge to inform equitable treatment. The corresponding challenge is to also educate policymakers of the difference between *equitable* and *exactly the same*—the two are not synonymous. Many see “equal under the law” as meaning “to be treated exactly the same”; however, applying policies made for men in exactly the same way to women does not constitute equitable treatment.

Female Inmates

Females represent the fastest-growing incarcerated population, with a rate faster than that of their male counterparts. This needs special attention because, even with a greater rate of growth, this is an area in which female offenders have perhaps remained the most invisible. Despite the greater rate of growth, there are still fewer female inmates than men; they are often incarcerated for less serious offenses; and they are rarely associated with violence in prison, rioting, or other assaultive behavior. There are, however, important gender-specific issues that female offenders face while in prison.

In early jails and prisons, female, male, and youthful offenders were placed in the same institutions without regard to safety, exploitation, or other issues of vulnerability. As the theory of penology changed, so did the manner in which individuals were incarcerated. By the early 20th century, most jails and prisons segregated males and females, either in separate institutions or separate within the same institution. These earlier separate, and seemingly equal, institutions were in fact equal only at face value. The earliest facilities for women were designed to rehabilitate the offenders such that they would conform to gender-related societal standards. In other words, women were taught how to be better cooks and better cleaners, and to perform other traditionally female-oriented roles so that they could be “better” daughters or wives. Because the purpose of their incarceration was rehabilitation, their sentences were typically indeterminate, meaning that they did not serve a fixed amount of time (although there was typically a maximum sentence to be served). These female inmates would be released when they were deemed rehabilitated. During this same time frame, though, men were sent to prison primarily for punishment and were released on the basis of a fixed sentence. The result of these different systems was that women often served more time than men for similar offenses.

In the 21st century, punishment remains the primary goal of incarceration for both males and females. Therefore, it would seem that the nature of the incarceration would be the same for both, yet this is not the case. As mentioned earlier, perhaps the most troubling difference is that the rate of incarceration for females has continuously outpaced that for men for the past decade. It is important to note that the “get tough” and harsh crime control policies of the late 20th century have seemingly had the greatest impact on female offenders. The biggest policy area that affects female offenders, though, has been that associated with the war on drugs.

The earlier discussion of female offender pathways highlighted the reasons why many women become involved with illegal drugs or develop substance abuse problems. The underlying addictions and associated criminal behavior, for many women, are symptomatic of their troubled lives and untreated trauma and other mental health issues; as a result, comorbidity (i.e., having more than one problem) is a significant problem in women’s prisons. The war on drugs, with a heavy reliance on incarceration as a solution, has been the most prevalent form of “treatment” many female offenders have received.

Unfortunately, prison has not proven an effective place in which to treat the very complex issue of drug addiction, especially for a population of women who are likely un- or underemployed, undereducated, economically marginalized, and who have untreated physical or mental health problems and are responsible for the care of young children. Many scholars, feminist or otherwise, believe that the problems of addicted individuals could be better served in the community with social-service-based help.

It should also be noted that over two thirds of women are responsible for caring for their dependent children prior to incarceration, compared with less than half of men. Furthermore, if a mother goes to prison, her children are more likely to be cared for by a relative, friend, or someone other than the child's father; however, when a father is incarcerated, his children are likely to be cared for by the mother. Thus, incarceration policies that disproportionately affect female offenders have often been thought to have collateral consequences for the children left behind. Because there are fewer female inmates, nationally, than male inmates, there are also fewer female facilities. Facilities for females, and for many men, are often located at distances too far away from families to allow for visits. These women tend to come from economically marginalized families who cannot afford visits far from home, so many children will not see their mother while she is incarcerated. This is an unfortunate situation, because research has demonstrated that increased family visits and support reduce the likelihood of recidivism and overall success in the community.

The nature of female incarceration has received much less attention than male incarceration. The number of female inmates, relative to males, is often referenced as the reason for the lack of research attention; however, the current literature suggests some important distinctions in what it means to do time in a female institution compared with a male facility. Sexual assault of inmates by inmates is much more prevalent in male facilities. The culture in a female facility, though, is more likely to involve consensual sex and to sometimes be part of pseudofamilies developed in prison. When sexual abuse does occur in a prison facility, it is likely to occur at the hands of staff. These abuses often go unreported or are not investigated. There is not an adequate infrastructure in place to deal with these types of institutional-based abuse. Only recently have states begun to criminalize sexual abuse of female inmates by staff, recognizing that females are in vulnerable positions relative to the status and power of prison staff and are never in a position to have consensual sexual relationships with staff.

Women in prison, similar to women in society at large, are overly controlled. Relative to male inmates, females tend to receive more write-ups and misconduct violations. However, the nature of write-ups and misconduct reports are for minor violations of institutional rules (e.g., not following orders, being insubordinate) instead of violence within the institution. Although the nature of the prison environment for women is much less violent than it is for men, female inmates are nonetheless considered a more difficult population to work with. Correctional staff often cite female offenders' reluctance to follow orders without question as one of the main reasons for this difficulty, as well as women's greater emotional needs.

Women do have greater untreated mental health, and often physical health, needs compared with male offenders. This is often due to women's greater histories of emotional,

physical, and sexual abuse and related untreated trauma. Female inmates are significantly more likely than male inmates to have suffered abuse as both children and as adults. The physical and mental health care of incarcerated females are often inadequate for their needs.

The smaller number of female inmates has also contributed to a shortage of research, attention, and money applied toward women's in-prison programming. Mental and physical health in prison was mentioned earlier, and women's vocational and educational programming, relative to male inmates', also has remained inadequate. There are not enough existing programs to teach women vocational skills that will help them earn a living wage on their release from prison. These types of programs are much more likely to be found in male facilities.

An important consequence of fewer female inmates is that there are fewer female facilities. Not only are these facilities located long distances from the female offenders' homes, but also there are rarely separate facilities for females based on risk level. Although most female offenders represent a low risk to institutional security, the ability to segregate female offenders by low, medium, and high risk is often missing. All female offenders serve time in the same facility, regardless of classification level.

Women as Victims

The connection between a girl's or woman's victimization and her offending is a complex yet important one for scholars of gender and crime to understand. Many women are neither simply victims nor simply offenders; they are often both. In fact, many women were victims long before they ever became offenders. Gender-focused research has highlighted female offenders' roles as victims. It is not uncommon for women to have been victims of physical, sexual, and/or emotional abuse, often at the hands of family members or loved ones.

Girls often exhibit the first signs of attempting to survive abuse at home by engaging in "survival crimes," namely, running away and engaging in sex work. These two behaviors, the first of which is considered a status offense for juveniles, offer viable means of escape from abusive homes. Often, girls do not see any other options available to them. Life on the street for young girls can be dangerous and may in fact lead to other means of survival, especially those related to drugs and drug use.

Although males are most certainly abused in the same ways as females, they are not abused at the same levels, and their abuse tends to end as they enter their teens (because they can fight back). Furthermore, much of the victimization of females is a result of male violence. In adulthood, this victimization may also expand into the economic realm, creating situations that trap women in abusive relationships. The situation is compounded for women who have children, because they often are not in a position to adequately provide

economic support for the children on their own. Unfortunately, this lack of economic power as an individual or within a household equates to less power and a lower likelihood of feeling safety in leaving an abusive relationship.

Regardless of the specific situation, women are often held in positions that are deemed secondary to men and that contain less power. This leaves girls and women vulnerable to violence in various forms. Men commit violence against women that serves to humiliate, dominate, and oppress as part of a patriarchal system that values men over women in most situations. When women do commit violence against men, it is often done in self-defense after a long period in a violent situation.

Feminist scholars have noted that it is more than a coincidence that much of the violence perpetrated against women has been done at the hands of males, often males known to the victim. This is true in all types of victimization. The majority of female rape and sexual assault victims know their assailants. Women who are already involved in physically abusive relationships are also more likely to become victims of sexual assault. Similar patterns are observed when we look at victims of physical abuse as well—most women know their assailants. Furthermore, it is statistically rare for mass-killing victims to be male; indeed, most serial killers are males, and most of their victims are females.

Why are women more likely than men to be victims of intimate violence? The best answer seems to be that male expression of violence is a way to exhibit control and power over women, either subconsciously or otherwise. It was, for a time, the nature of rape laws that only females were specified as victims and, even earlier, rape laws were in place mainly because women were considered property of men. Punishment was not for the benefit of the woman herself but to provide justice to the person who “owned” her. Society has continuously given off similar, albeit more subtle, messages. More contemporary messages center on women as in need of control by and protection from men. This is but one way women are placed in disadvantaged positions that make them more vulnerable to abuse at the hands of men.

It matters that women are often abused by men they know. First, women who are exposed to abuse from those who are supposed to care for them have greater difficulty forming healthy relationships. Second, when the victim of physical abuse or a sexual assault knows the assailant or is socially close to the assailant, the likelihood of prosecution decreases. In other words, the closer the social relationship, the less likely it is that the assailant will face any punishment. This perpetuates a societal structure and sends a message to men that women are “safe” targets for victimization.

Violence against women—sexual, physical, or otherwise—is not simply an individual problem. This is one of the most important messages of feminist scholarship. The patriarchal structure that allows so much victimization,

often without any recourse for women, is a social as well as an individual problem. Until there is a significant change in the way that women are valued within society, it is likely that they will continue to experience higher rates of victimization, which increases the odds of their substance abuse, offending, and official criminal justice participation.

Conclusion

Scholars in the area of criminology should continue to think of gender not as just another variable but a matter worthy of specific focus and theorizing, especially with regard to female offending. More needs to be discovered not only about how women’s unique pathways affect offending but also how this knowledge can be used to better the lives of the increasing numbers of girls and women who find themselves in the criminal justice system. In particular, much more work needs to be accomplished to help us understand how women’s pathways to offending might best be addressed so that their levels of offending, recidivism or reoffending, and rates of incarceration can be reduced.

Research into effective treatment and supervision for female offenders should be expanded. Best practices are currently the standard in policy-based applications in this field yet, in the 21st century, the majority of standards- or evidence-based policy is still based on research conducted largely with only males or male offenders. The relevance of gender in the criminal justice system cannot be overstated; it warrants greater attention to and movement away from the historical invisibility often afforded the female offender and toward more gender-informed policies and practices.

GUNS AND CRIME

GARY KLECK

Florida State University

On June 26, 2008, the Supreme Court handed down one of the most intensely awaited decisions in its recent history, holding that the Second Amendment recognizes an individual right to keep and bear arms, and not merely the right of states to maintain armed militias (see Cottrol, 1994, for a good overview of the constitutional issues linked with the gun control debate). The decision, minority opinion, and supporting briefs all cited dozens of scholarly studies bearing on the links between guns and violence. This chapter summarizes that literature.

The Use of Guns in Crime

Firearms are heavily involved in crime in America, especially homicide. In 2006, approximately 11,600 homicides were committed by criminals armed with guns, claiming 68% of all homicides (U.S. Federal Bureau of Investigation, 2008a), and an additional 100,000 to 150,000 individuals are medically treated for nonfatal gunshot wounds each year (Kleck, 1997, p. 5; see also Annett, Mercy, Gibson, & Ryan, 1995). Data from the National Criminal Victimization Survey (NCVS) indicate that as many as 500,000 violent crimes were committed in the United States in 2006 by offenders armed with guns (though not all of these involved the perpetrators actually using the guns, as distinct from merely possessing them

during the incident). About 26% of robberies and 7% of assaults were committed by gun-armed offenders (U.S. Bureau of Justice Statistics, 2008).

Compared with other industrialized nations, the United States has higher rates of violent crime, both fatal and non-fatal, and a higher rate of gun ownership (Kleck, 1997, p. 64). These facts have led many people to conclude that America's high rate of gun ownership must be at least partially responsible for the nation's high rates of violence, or at least its high homicide rate. This belief in a causal effect of gun levels on violent crime rates has in turn led many people to conclude that limiting the availability of guns would substantially reduce violent crime, especially the homicide rate.

It is not so widely known, however, that large numbers of crime *victims* in America also use guns in the course of crimes, in self-defense. The best available evidence, based on 16 national surveys of probability samples of the adult U.S. population, indicates that guns are used by victims in self-protection more often than crimes are committed by offenders using guns. For example, victims used guns defensively approximately 2.0 to 2.5 million times in 1993, compared with approximately 850,000 crimes in which offenders possessed guns (Kleck & Gertz, 1995). Although some scholars have speculated that surveys overestimate the frequency of defensive gun use, there is no empirical evidence to support this conclusion (Kleck & Kates, 2001, pp. 241–264).

Scale and Patterns of Gun Ownership in America

By international standards, the share of U.S. households with guns is very high. In national surveys, 40% to 50% of U.S. households report having one or more guns; the nearest known foreign competitor is Switzerland, where about one third of households have guns, mainly because of military service requirements (Killias, 1990). There were probably more than 276 million guns in private hands in the United States at the end of 2003, about 36% of them handguns. The size of the U.S. gun stock, especially the handgun stock, increased enormously from the 1960s through the 1990s, although the share of U.S. households with guns showed little change over that period (Kleck, 1997).

One obvious policy implication of this huge existing stock is that a large supply of guns would remain available, to criminals and noncriminals alike, even if all further manufacture and importation of guns were immediately halted (Kleck, 1997, Chap. 3). In contrast, only a few hundred-thousand guns are used to commit violent crimes each year. Thus, the supply of guns is hundreds of times larger than the numbers needed for criminal purposes. Consequently, even very large decreases in the supply would not produce gun scarcity but instead would merely reduce the size of the surplus. On the other hand, this does not imply that gun possession cannot be reduced among criminals or other high-risk subsets of the population, because it is possible that members of these groups can be deterred by legal penalties from acquiring or possessing guns, no matter how many are circulating.

The broad patterns of gun ownership in America do not support, in any straightforward way, the general idea that higher gun ownership rates will lead to higher violence rates, because gun ownership is generally highest in those groups where violent behavior is lowest. Although both gun ownership and violence are more frequent among males and Southerners, gun ownership is also higher among whites than among African Americans, higher among middle-aged people than among young adults, higher among married than unmarried people, higher among richer people than poor, and higher in rural areas and small towns than urban areas—the opposite of the way that violent crime is distributed (Kleck, 1997, Chap. 3).

Crime-Related Motives for Owning Guns and the Effect of Gun Levels on Crime Rates

The vast majority of Americans who own handguns own them primarily for protection against crime (63% in one national survey), and about half of all gun owners, including those who own rifles or shotguns, own them primarily for protection (Cook & Ludwig, 1997, p. 38). Still other

owners cite protection as one of their reasons for having guns, secondary to hunting and other motives unconnected with crime. On the basis of the stated motives of gun owners, then, ownership of firearms is a response to crime, not just a cause of it.

This in turn suggests that higher crime rates could contribute to higher rates of gun ownership, as well as the reverse. Many research studies have provided empirical evidence that higher crime rates may indeed cause higher gun ownership rates (summarized by Kovandzic, Schaffer, & Kleck, 2005). The principal significance of this possibility is that it complicates the interpretation of research that finds more crime and violence in the same places and times as more gun ownership. It raises the question “Do more guns lead to more crime, or does more crime lead to more people acquiring guns for self-protection, or both?” When there is a possibility of this sort of two-way causation, separating one effect from the other becomes very difficult, requiring the use of highly complex statistical procedures. This chapter is not the place to address such technical matters; it suffices to say that experts continue to disagree about whether anyone has solved those statistical problems.

How Do Guns Affect Crime?

Understanding the connection between guns and crime requires appreciating three fundamental facts:

1. Whereas gun ownership affects crime in various ways, crime also affects gun ownership.
2. The possession and use of guns have both violence-reducing and violence-increasing effects.
3. The kinds of effects that possession and use of guns have on crime depend on who possesses and uses them. The effects of victims using guns for self-protection are predominantly violence reducing, whereas the effects of criminals using guns for aggressive purposes are a mixture of violence-increasing and, more surprisingly, violence-reducing effects.

Because gun effects are quite different depending on what sort of person possesses the gun, the effects of offender possession/use and victim possession/use are discussed separately. Readers should, however, keep in mind that many crime victims are themselves criminals. Indeed, crime victimization is far more common among criminals than among noncriminals, and serious violent victimization is largely concentrated among criminals. For example, research has found that over 60% of homicide victims have an arrest record. Thus, serious violence is largely a criminal-on-criminal phenomenon. It therefore would be a mistake to view the offender–victim distinction as equivalent to the distinction between wicked offenders and morally pure victims. On the other hand, it would be equally erroneous to believe that in individual incidences of violence there is no real distinction between offenders and victims or that it is impossible to tell which party is the

aggressor and which is the victim. The somewhat morally unsatisfactory reality is that many of the people who are, in a given violent crime, clearly the victims of violence initiated by another person have themselves committed serious crimes in the past.

One critical implication of these facts is that even criminals use guns for genuinely defensive purposes, in incidents in which they are victims as well as for offensive or aggressive purposes in incidents in which they are offenders. Although this is almost never a part of the political debate over guns, even criminal gun possession can have violence-reducing effects as well as violence-increasing effects. Defensive uses of guns by criminals are not likely to be reported to either police or to survey interviewers, but there are nevertheless strong reasons to believe that they occur frequently and that they have the same effects as defensive uses by noncriminals.

Crime-Increasing Effects of Offender Possession and Use of Guns

Incidents of violent crime can be seen as proceeding through as many as four possible stages: (1) threat, (2) attack, (3) injury, and (4) death. The more serious a violent crime, the more of these stages the incident proceeds through. To even qualify as a violent crime, an incident must involve an aggressor, at minimum, threatening another person by word or gesture. Threat may or may not be followed by attack (i.e., an attempt to physically injure the victim). This attempt may or may not be successful (i.e., result in the victim being injured). If an injury is inflicted, it may or may not result in death. Whether the aggressor possesses a gun can affect the occurrence of each of these possible events (Kleck & McElrath, 1991).

Threat

Making a threat of violence against another person typically involves contact with another person—that is, an aggressor and victim come together in the same place at the same time. The aggressor's willingness to confront the victim may be influenced by weapon possession, because having a weapon can give the aggressor the confidence that he or she can dominate and control the encounter and avoid being hurt himself or herself. Thus, higher rates of gun possession among prospective aggressors could increase the rate of violent encounters. There is, however, no empirical evidence directly bearing on this question.

Attack

Similarly, the aggressor's possession of a gun could embolden him or her to go beyond a mere threat and attempt to inflict injury on the victim. A gun might also make it more feasible to successfully act on this willingness to attack, because some attacks are unlikely, or impossible,

to be carried out without a gun. Many have referred to the gun as an "equalizer," usually referring to the fact that a powerful weapon can make a victim the equal of a bigger, stronger offender. The same, however, is true for aggressive actions—an aggressor may be more willing to initiate attacks against more powerful victims because the aggressor possesses a gun. Research (Kleck & McElrath, 1991) has shown that gun use by offenders is more common in violent crimes in which less powerful aggressors attacked more powerful victims; that is, offender gun use is more common when the offenders were outnumbered by the victims; more common when women attacked men than when women attacked other women; and more common when offenders outside of the physically prime years—younger than 14 or older than 40—attacked victims in their prime years. In other words, guns seem to facilitate attacks by less powerful offenders against more powerful victims. Attacks that would otherwise have been unlikely were more feasible because the prospective aggressor possessed a gun.

Likewise, effective attacks at a distance are virtually impossible without a gun. Although little serious violence is inflicted at great distances, those that are, such as sniper attacks, virtually require gun possession to commit them. Furthermore, some scholars have speculated that some would-be aggressors would not be willing to attack others if doing so required that they do something as distasteful as coming into direct physical contact with their gun. The very fact that guns facilitate attack at a distance, even if it is a matter of a few feet, may encourage attacks by aggressors who psychologically need a more "antiseptic" mode of attack.

In addition to facilitating attacks—that is, making them possible or easier to commit—possession of guns by prospective aggressors has also been claimed to trigger attacks. Discussed in the psychological literature under the rather vague term *weapons effect*, this hypothesis asserts that "the trigger pulls the finger"; that is, that possession of a gun can trigger or release an impulse to aggress. The theory behind this is that if a person is already angered, and in that sense ready to aggress, even the sight of a gun, or its possession, can trigger the aggressive impulse, because of the learned association between guns and aggression. The research on this hypothesis is almost equally divided between studies supporting it and those failing to do so. The more realistic experimental studies, however, generally do not support it.

This lack of experimental support could be due to yet another effect of weapon possession, which may have the opposite effect on attack. For some people, exposure to weapons appears to inhibit aggression. If an attacker wants to injure, but not kill, a victim then possession of a deadly weapon gives him or her more ability to kill than he or she might be willing to use. Because most aggressors have less-than-lethal intentions, most of them may perceive guns this way, causing many to refrain from attacking at all rather than risk killing their victim.

Offender possession of guns also can discourage attacks by making them less necessary to the accomplishment of the aggressor's goals. For example, a robber's primary goal is obtaining a victim's property, which is accomplished by intimidating the victim. Although intimidation might be achieved through an attack, it is usually achieved through threats alone—most robberies do not involve injury to the victim. One of the most strongly and consistently confirmed findings in the literature on guns and violence is that robbers with weapons are *less* likely to attack and injure their victims than robbers without weapons (Kleck & McElrath, 1991). By 1997 alone at least 18 studies had been conducted that, without exception, confirmed this fact. This phenomenon can be labeled a *redundancy effect*, because gun possession makes it unnecessary for the aggressor to actually attack the victim. Merely threatening to attack is sufficient to induce the victim to comply, because the weapon is perceived as such a lethal one. In contrast, many robbers without weapons must attack their victims at the outset of a robbery, as a way of immediately gaining control.

The redundancy effect is not limited to robbers. People committing assaults, without any intent to steal, are also less likely to actually attack their victims, instead of confining their aggression to a threat, if the assaulter possesses a gun. An assaulter's goal may be to terrify or humiliate his victim, but if the aggressor has a gun these goals can also be achieved without actually attacking the victim. The moral irony of these facts, of course, is that guns in the hands of "bad" people have some "good" effects. This moral complexity may explain why these effects are rarely addressed in the public debate over guns. It is easier to think in black-and-white terms, and the idea that empowering bad people could have any good effects is unthinkable to some people.

Nevertheless, the evidence indicates that, when one takes into account all of these various gun effects on attack, the net effect of offender gun possession is that it reduces the likelihood of attack.

Injury

If an attack does occur, it may or may not result in injury (e.g., by a bullet reaching its target, a knife penetrating skin, or a fist or club bruising flesh or smashing bone). The attributes of weapons that can facilitate attack may also reduce the attack completion rate by encouraging attacks at a longer range, against more formidable opponents, or under more difficult conditions. It is possible to shoot a victim from a great distance, but the rate at which this is achieved is lower than the share of thrown punches that strike the victim. Regarding the more common close-range gun attacks, people unfamiliar with firearms marksmanship might assume that shooters are virtually certain to hit their target. In fact, NCVS data covering the United States from 1987 to 1992 indicate that only 18% of incidents in which an attacker shot at a victim

resulted in the victim suffering a gunshot wound, whereas about 45% of knife attacks result in a knife wound (Kleck, 1997, Chap. 5). The rate of success in an aggressor inflicting injury on a victim is far lower in attacks with guns than in attacks with knives and other attacks.

Even individuals trained and presumably emotionally prepared to shoot under stressful conditions, such as police officers, usually cannot hit their targets. Police shooting policies usually forbid firing warning shots, and thus when the officers fire their guns they intend to shoot suspects. Nevertheless, police officers were able to inflict one or more gunshot wounds on an adversary in only 37% of the incidents in which they intentionally fired at someone (Kleck, 1997). This success rate is probably even lower among civilians, who have not had the training and experience of police officers, and the NCVS data support this expectation. Thus, there is strong reason to believe that the net effect of offender gun use in violent crimes is that it decreases the fraction of attacks resulting in injury.

Death

About 1 of 7 assaultive gunshot woundings known to the police results in death (Kleck, 1997). Because many less serious nonfatal gunshot woundings never come to the attention of authorities, the true death rate is almost certainly lower than this. Nevertheless, gunshot wounds are more likely to result in death than are those inflicted by a knife, the weapon that is generally assumed to be the next most lethal among those that could be used in the same circumstances as guns. Most police-based and medical studies indicate that gunshot woundings are about three to four times more likely than knife woundings to result in the victim's death (Kleck, 1997).

One of the central mysteries of the guns–violence field is the degree to which the higher fatality rate of gunshot attacks is due to the greater inherent lethality of firearms or to the greater degree to which people who use guns with which to attack are more willing to kill their victims. In other words, is the difference in fatality rates due to differences in weapon lethality or differences in attacker lethality? Attackers do not randomly choose their weapons or merely use whatever is available. It is a rare gun homicide that occurs when a knife or blunt instrument is not also available, and all gun killers obviously also have hands and feet with which they could have attacked the victim. Thus, guns are *chosen* by aggressors over other available weapons. Furthermore, scholars generally agree that aggressors choose weapons suited to their goals and that the aggressors who choose guns probably have more lethal intentions than those who choose knives. Consequently, some of the higher fatality rates of gun attacks are due to attacker differences instead of weapon lethality differences. Unfortunately, unless one can somehow measure and control for attacker lethality in assaults, it is logically impossible to use data on assault fatality rates to separate

the effects of a weapon's technical properties from the closely associated effects of the attacker's willingness to seriously hurt the victim.

The comparison of gun lethality versus knife lethality, however, is something of a red herring, or at the very least a distraction from more policy-relevant issues. The vast majority of existing gun laws and proposed control measures apply exclusively to, or with greater strictness toward, handguns, whereas long guns, such as shotguns and rifles, are left relatively unregulated. Thus, many offenders are free to substitute long guns when handgun-only controls deny them the preferred handgun. Most homicides are committed under circumstances in which it was not essential that a handgun be used (concealability or easy portability of the weapon was not essential), so the substitution issue that is most frequently relevant to debates over handgun controls is the substitution of long guns for handguns, not the substitution of knives for guns.

There is little doubt that long guns are more lethal than handguns. Shotguns fire more projectiles, and create more wounds, than handguns, whereas rifles fire bullets at a higher velocity, producing wounds with greater penetration into the victim's body. Long guns are also more accurate than handguns; a shooter using a long gun is more likely to wound the victim. To the extent that handgun controls attain their proximate goal of denying handguns to at least some prospective attackers, but do not significantly restrict access to long guns, they are more likely to lead to substitution of more lethal weapons than less lethal ones. The policy implication is that if a subset of the population is to be legally denied guns, the restriction should cover all gun types, not just handguns.

Offender Gun Use in Robbery

Weapon effects in the context of robberies merits its own separate discussion. Gun effects may differ from those in assaults, because the robber's primary goal is to obtain the victim's property, and threats or use of force are largely tools for achieving that goal. About 25% of robberies involve offenders armed with guns, and about 5% of all homicides that occurred in 2006 were committed with guns and linked with robbery (computed on the basis of statistics from the U.S. Federal Bureau of Investigation, 2008a). The effects of offender possession and use of guns on the frequency and outcomes of robberies are quite complex, but research supports the following conclusions:

1. Total gun ownership levels (criminal and non-criminal combined) have no net effect on total robbery rates. On the other hand, we do not know the impact of gun ownership among criminals, or rates of gun carrying—and thus the immediate availability of guns for robbery—on robbery rates.

2. Higher gun ownership levels probably increase the rate of gun robberies, and decrease the rate of nongun

robberies, thereby increasing the fraction of robberies involving guns.

3. Injuries are less common in gun robberies than in nongun robberies; therefore, decreases in gun use among robbers would probably increase the fraction of robberies that result in injury.

4. When injuries are inflicted on robbery victims, those inflicted by gun-armed robbers are no more likely to result in hospital treatment of some kind than those inflicted by other robbers. Injuries inflicted by gun-armed robbers are more likely to result in hospitalization overnight than those inflicted by unarmed robbers, but they are about the same in this respect as injuries in knife robberies and somewhat less likely to result in overnight hospitalization than injuries inflicted by robbers armed with weapons other than guns or knives. Thus, there is currently no empirical basis for believing that if knives were substituted for guns, the fraction of injuries requiring hospital treatment or overnight hospitalization would decrease.

5. Robbers armed with guns are more likely to obtain the victim's valuables. This is partly due to the fact that victims are less likely to resist gun-armed robbers. Thus, if fewer robbers were armed with guns, more victims would probably manage to retain their property.

6. Guns enable robbers to tackle more lucrative and risky targets, such as businesses, instead of more vulnerable ones, such as women, children, and the elderly. Reducing gun availability could cause robbers to switch from the former to the latter targets, shifting the burden of robbery to those most vulnerable to injury and least able to bear the financial losses.

7. Gun robberies are more likely than nongun robberies to result in the death of the vulnerable victims. It is unknown, however, whether this is due to the lethality of guns or the greater willingness to kill of robbers who use guns. Gun reductions therefore may or may not produce any reduction in robbery murders, depending on the impact of gun scarcity on (a) the number of robberies; (b) how much of an increase in the number of injuries this causes; and (c) how much the fatality rate declines among this increased number of injuries, assuming it declines at all. The issue is further complicated by the fact that most gun control legislation restricts primarily or only handguns, but most incarcerated felons say they would substitute long guns, such as sawed-off shotguns, if they could not carry handguns. This suggests that laws that reduce only the availability of handguns would increase the fraction of robbery attacks resulting in death by inducing the substitution of more lethal long guns.

In sum, gun control policies that reduce gun possession among robbers would have the desirable effect of decreasing the rate at which robbers obtain their victims' property, and they might or might not reduce the number of robbery

victims killed. On the other hand, gun scarcity would also probably increase the number of robbery injuries and shift the burden of victimization to victims less able to bear the burden, without reducing the number of robberies and without necessarily reducing robbery killings. Therefore, it is unclear whether the overall set of social consequences of gun scarcity would be favorable with regard to robbery.

Crime-Disrupting Defensive Effects of Victim Use of Guns

Defensive gun use by crime victims is both common and effective in preventing injury to the victim and property loss. People who use guns during crime incidents are less likely to be injured or lose property than people who either adopt other resistance strategies or do not resist at all. These effects are usually produced without shooting the gun and are almost always produced without wounding or killing the criminal: Only 24% of gun defenders even fire the gun (including warning shots), only 16% try to shoot the perpetrator, and at most 8% wound the offender (evidence summarized in Kleck, 1997, Chap. 5).

Victims' defensive use of guns almost never angers or otherwise provokes offenders into attacking and injuring the resisting victims. It is extremely rare that victim gun use is followed by injury to the victim, and some of these few injuries would have been inflicted anyway, regardless of victim resistance. In any case, it is clear that, regardless of whether victim gun use occasionally provokes offender aggression, the net effect of victim gun use is to reduce the likelihood that the offender will hurt the victim.

The largest, most nationally representative samples of crime incidents on which we have information about victim resistance strategies and their consequences are drawn from the NCVS, conducted by the U.S. Census Bureau. The most extensive analysis of these data was conducted by Tark and Kleck (2004). They found that, among 45 sample cases of victims who used a gun to attack the offender, none were injured after using the gun, and of 202 sample cases of victims who used a gun to threaten the offender, just 7.7% were injured after using the gun. They also found that victims who resisted with a gun typically did so under more dangerous and difficult circumstances than victims who used other strategies (e.g., when the victim faced offenders who were armed, when the victim was outnumbered by the criminals, or when the victim was already injured). If one takes into account these greater dangers, victim gun use appears to be even more effective in preventing injury than the already very low injury rates suggested.

The impression from earlier studies that victim resistance increases the odds of being injured appears to be the product of a simple research error: the failure to take account of which came first, victim resistance or injury. Crimes in which a resisting victim was injured turn out to consist almost entirely of incidents in which the victim resisted *after* the offender attacked and injured him

or her (i.e., the injury provoked victim resistance; resistance did not provoke the offender to inflict injury) (Kleck, 1997).

Early pro-control propaganda often claimed that when victims attempt to use guns defensively, offenders often take the guns away from them and use them against the victim. This is false. The only significant factual foundation for this claim appears to be the fact that police officers are occasionally killed with their own guns. This phenomenon is, however, extremely rare (it happened just once in the United States in all of 2006) and not as relevant to the issue of defensive use of guns as it seems. From 1997 through 2006, an annual average of 4.8 police officers in the United States were killed with their own guns, out of a total of 665,555 full-time sworn officers in the nation. Furthermore, these extremely rare incidents typically do not involve the officer attempting to use the gun defensively; instead, they usually involve the suspect snatching the gun from the officer's holster or stealing it from his or her vehicle. Thus, the officer's gun was available to be obtained by the criminal suspect because the officer was not using the gun for self-protection (Kleck, 1997, pp. 168–169; U.S. Federal Bureau of Investigation, 2008b).

Deterrent Effects of Gun Ownership Among Potential Victims

Evidence also indicates that some criminals may be deterred from making criminal attempts in the first place by the possibility of victims using guns against them. Criminals interviewed in prison indicate that they have refrained from committing crimes because they believed a potential victim might have a gun (Kleck, 1997). Likewise, anecdotal evidence indicates that crime rates have dropped substantially after highly publicized instances of prospective victims arming themselves or being trained in gun use, or victims using guns against criminals. Evidence also supports the hypothesis that U.S. burglars are careful to avoid residences where the victims are home because they fear being shot. Whereas 43% of British residential burglaries are committed while victims are home, only 9% of residential burglaries in the United States are committed under such circumstances (research summarized in Kleck, 1997, Chap. 5). None of this evidence is strong or decisive; instead, one can say only that it is consistent with the hypothesis that criminals are deterred from attempting some crimes by the possibility of confronting a victim with a gun.

The Net Effect of Gun Ownership Levels on Crime Rates

The research on gun use by victims has yielded very consistent results: It reduces the likelihood of injury or property loss. Thus, gun possession among largely noncriminal

prospective victims has beneficial effects. On the other hand, gun possession among criminals has a mixture of both harmful and inadvertently beneficial effects. Consequently, the net effect of overall gun ownership levels on violence rates is not self-evident on the basis of the research discussed earlier.

Dozens of studies of the effect of gun ownership levels on crime rates in macrolevel units such as cities and states have been conducted, but most of the research is seriously flawed. In particular, most studies have failed to properly model the possibility of a two-way relationship between violence rates and gun ownership rates, making it impossible to interpret the meaning of a positive association between the two (Kleck, 1997). Although more guns may lead to more crime, higher crime rates may motivate more people to acquire guns for self-protection. Likewise, most of these studies did not use measures of gun levels that are known to be valid—the researchers were actually measuring something other than gun ownership levels, making it impossible for them to assess the effect of gun levels.

Most of this research has found no effect of gun levels on rates of robbery or aggravated assault. The evidence on homicide rates, on the other hand, is much more mixed, although studies that have used validated measures of gun ownership and that addressed the possible two-way causal relationship mostly have found no net effect of gun levels on homicide rates (Kleck, 1997, Chap. 7). The most sophisticated recent research indicates that the net effect of overall gun ownership (both criminal and noncriminal gun ownership combined) on homicide is actually negative; that is, overall gun levels *reduce* the homicide rate, probably because the homicide-reducing effects of noncriminal gun ownership outweigh the homicide-increasing effects of criminal gun ownership (Kovandzic et al., 2005). Because this research relied on highly complex statistical procedures, however, one can be confident that these findings will be challenged.

How Do Criminals Acquire Guns?

Some scholars have asserted that professional gun traffickers (i.e., criminals who illegally sell substantial numbers of guns for profit) are significant sources of guns for criminals. The best available evidence, however, fails to support this claim. To be sure, burglars and other thieves sell guns that they come across in their criminal activities, but they average fewer than 4 guns a year, and some of these are sold to noncriminal buyers. Illicit gun selling is almost all done at a very low volume. Typical trafficking operations uncovered by law enforcement authorities handle fewer than 7 guns each, and the federal Bureau of Alcohol, Tobacco and Firearms uncovers fewer than 15 high-volume (> 250 guns) operations in the United States each year. High-volume trafficking probably supplies less than 1% of the guns in criminal hands.

Trafficking activity apparently has no measurable effect on levels of gun possession among criminals, or on violent crime rates. One likely explanation would be that nearly all traffickers' potential criminal customers have other sources of guns (especially the pool of locally stolen guns) and are not dependent on traffickers. Consequently, even the best-designed strategies aimed at reducing gun trafficking are unlikely to have any measurable effect on gun possession among criminals or on violent crime rates (Kleck & Wang, in press).

Instead, theft appears to be crucial as the mechanism that brings guns into criminal hands. NCVS data indicate that at least 400,000 to 600,000 guns are stolen each year, a number many times higher than any evidence-based estimate of the volume of trafficked guns (Kleck & Wang, in press). As a result, at any one time there are millions of stolen guns circulating among criminals. The volume of gun theft is so large that, even if one could completely eliminate all voluntary transfers of guns to criminals, including either lawful or unlawful transfers, and involving either licensed dealers or private citizens, and even if police could confiscate all firearms from all criminals each year, a single year's worth of gun theft alone would be more than sufficient to rearm all gun criminals and supply the entire set of guns needed to commit the current number of gun crimes (Kleck, 1997, pp. 90–94). Interviews with incarcerated felons indicate that most guns acquired by criminals were probably stolen at some time in the past (Wright & Rossi, 1986).

Most gun theft is a by-product of residential burglary and other thefts from private owners. Less than 2% of stolen guns are stolen from gun dealers. Criminals do not typically go out looking for guns to steal but instead steal those they happen to come across in the course of crimes, most commonly in thefts from homes or vehicles. They usually sell the guns they steal, but most gun thieves have also retained at least one gun in their careers for their own use. They typically do not keep the gun not because they did not already have one but because the stolen weapon was “a nice piece.” Thus, criminals most commonly use theft as a way of upgrading the quality of their weaponry instead of as a way of becoming armed (Wright & Rossi, 1986).

Wright and Rossi (1986, p. 185) found that 16% of the felons' handguns had been purchased from retail, presumably licensed, sources, probably because the criminals did not have any disqualifying criminal convictions at the time of purchase or because no background checks were required at that time. Surveys of incarcerated criminals also indicate that offenders believe they could get guns from multiple types of sources, so eliminating a single channel of guns usually would not prevent acquisition of a gun.

Conclusion

The widespread availability of guns in America affects crimes in far more complicated and surprising ways than is

generally known. Guns in the hands of crime victims have primarily violence-reducing effects, whereas guns in the hands of criminals have both violence-increasing effects and, more surprisingly, some violence-reducing effects as well. The implications for crime control policy are that gun control efforts should focus narrowly on depriving criminals from guns, because disarming victims and prospective victims would have predominantly crime-increasing effects. It would therefore be unwise to try to reduce gun availability among criminals by reducing it in the general population in the hope that this would reduce the flow of guns from noncriminals to criminals via theft. However, even the narrowly focused disarming of criminals will not necessarily have exclusively violence-reducing effects; criminal-centered gun control efforts will succeed only if the crime-increasing effects of guns in the hands of criminals are stronger than the crime-decreasing effects.

The control efforts most likely to minimize criminal gun use are those that operate most directly on the last links in the chain of possession of guns, just prior to a criminal using the gun to commit a violent crime. Thus, efforts to intercept guns while carried through public spaces on the way to a crime scene are more likely to be effective than efforts to restrict manufacture, importation, or retail sales of guns, because the causal chain resulting in criminal gun use is so much shorter and direct from gun carrying in public to use in a crime. Thus, one of the more promising approaches to reducing gun crime is improving the ability of police officers to detect concealed gun carrying and increasing their inclination to make arrests for unlawful carrying of firearms.

INTELLIGENCE AND CRIME

JOHN PAUL WRIGHT AND DANIELLE BOISVERT

University of Cincinnati

Intelligence is the most studied human characteristic in the world. Since World War I, millions of individuals across virtually every continent have taken intelligence tests. The information garnered from these tests has been subject to intense debate over the validity of the results and the interpretation of the patterns found. IQ (intelligence quotient, a score on any of several standardized tests), it seems, is an important predictor of life outcomes, such as the level of education one achieves and the amount of money a person will earn over his or her lifetime. IQ, however, is also linked to a number of social problems. IQ predicts the use of welfare and other social safety nets. It predicts the number of births one will have out of wedlock and, more important, it predicts criminal involvement. For these reasons, and more, it is fair to say that no other variable has generated as much debate or as much criticism as has IQ.

What Is Intelligence?

Definitions of human intelligence generally point to at least three characteristics. First, intelligence is best understood as a compilation of brain-based cognitive abilities. According to 52 eminent intelligence researchers, *intelligence* reflects “a very general mental capability that, among other things, involves the ability to reason, plan, solve problems, think abstractly, comprehend complex

ideas, learn quickly and learn from experience” (Ellis & Walsh, 2003, p. 343).

Intelligence comprises a multidimensional set of cognitive abilities that allow an individual to cognitively assess complex situations, use reason and logic to solve problems, and formulate adaptive behavioral responses to environmental situations and alter those responses when necessary. The collection of abilities that fall under the umbrella of “intelligence” provide an individual the ability to learn, to learn from mistakes, and to recall situations in which mistakes were made so that they will not be made again. In short, intelligence reflects a range of cognitive abilities, not just a single ability.

Second, IQ reflects the intercorrelations between these brain-based abilities. Virtually all studies find that the unique abilities that compose intelligence have a strong tendency to correlate with each other (Ellis & Walsh, 2003). Individuals who score high on measures of specific mental abilities, such as spatial visualization, are also more likely to score high on measures of other mental abilities. For example, people who are capable of using reason to solve problems are also more likely to be able to plan for the future, to seek out and to acquire information to make better informed decisions, and to be able to use that information to their advantage.

Third and finally, general intellectual abilities are hierarchical. Because unique intellectual abilities correlate strongly with a diverse array of other intellectual abilities,

their patterns of correlations can be subsumed under a broad, overall quantitative assessment of general intelligence. This quantitative assessment is referred to as *g*.

To understand the hierarchical nature of *g*, think of a professional athlete. The qualities that compose professional athletes are multidimensional. Many athletes are physically strong, can endure tremendous amounts of physical stress, and are highly competitive. These components are usually visible in the best athletes—that is, these athletic abilities correlate. Now, if we wished to assess an athlete's overall level of athleticism, we could score the athlete on each of the dimensions that compose our measure of athleticism and create an overall score. Psychologists do much the same to measure *g*.

How Is Intelligence Measured?

A range of intelligence tests have been created and intensively analyzed. Some of the better-known intelligence tests are the Stanford–Binet (e.g., Roid, 2005), the Wechsler Intelligence Scale for Children (e.g., Wechsler, 2003), the Wechsler Adult Intelligence Scale–Third Edition (Wechsler, 1997), the Wechsler Preschool and Primary Scale of Intelligence–Third Edition (Wechsler, 2002), and the Kaufman Assessment Battery for Children (Kaufman & Kaufman, 2002).

These tests have been found to meet the criteria for scientific acceptance. They have high test–retest reliability, and they predict important life outcomes (i.e., they have construct validity). They also appear to be valid indicators of an individual's overall level of intellect. No critical assessment of contemporary IQ tests has yet revealed substantial bias, and no critical assessment of these tests have proven them to be invalid measures of cognitive abilities.

To aid in comparing scores on IQ tests, scientists *statistically norm* the tests. Doing this allows individual scores to be compared with others' scores and ranked accordingly. Because of the norming of the tests, the distribution of *g* follows the mathematical properties of a normal curve. Under a normal curve, which resembles the shape of a bell, scientists can easily compute the proportion of individuals with a specific IQ. For example, intelligence tests have a mean (average) of 100 and a standard deviation of 15 points. Between ± 1 standard deviations (85–115 IQ points) falls slightly over 68% of the population; ± 2 standard deviations (70–130 IQ points) encompasses 95% of the population.

Genetic and Environmental Influences on Intelligence

The origins of IQ have been in dispute since its inception. Prior to the 1960s, researchers were influenced strongly by *hereditarianism*, or the belief that human traits can be

transmitted from parents to offspring through their genes. This perspective fell into disfavor in the 1960s and remained a politically incorrect research topic through the 1990s. Advancements in the genetic sciences at the turn of the 21st century, however, ushered in a new understanding of the origins of IQ.

No other discipline has done as much to inform us about the origins of IQ as has behavioral genetics. Behavioral genetics researchers use a variety of complex methods, including the use of large-scale twin studies, to dissect human behavior and traits into three main components: (1) the proportion of the variance in IQ associated with genes, (2) the proportion of variance in IQ attributable to environments that are similar for all family members (i.e., shared environments), and (3) the proportion of variance in IQ accounted for by environmental influences unique to individual family members (i.e., nonshared environments).

In the study of intelligence, examinations of identical (monozygotic [MZ]) and fraternal (dizygotic) twins are preferred, because they allow researchers to estimate the degree of heritability in complex traits. *Heritability* refers to the amount of variance in a trait or behavior—in this case, IQ—that is accounted for by genetic influences. Researchers use twin data because identical twins share approximately 100% of their DNA, whereas fraternal twins share only about 50% of their genetic makeup.

If IQ is 100% heritable, then MZ twins would be *concordant* on measures of IQ—that is, they would score roughly the same. IQ scores would, however, be less concordant between fraternal twins and should be uncorrelated between individuals chosen at random. Conversely, if environmental variables are responsible for IQ differences between individuals, then estimates of heritability should be reduced substantially, and they should not follow the patterns expected by genetic theory (i.e., with MZ twins correlating higher than dizygotic twins).

Numerous behavioral genetic studies have shown that, on average, genetic influences are pervasive across a range of human traits and behaviors. Virtually any human characteristic is genetically influenced. The remaining variation in human traits, however, is usually found to be associated with nonshared environmental influences, such as unique peer group associations or differential exposure to environmental toxins. Shared environmental influences, such as socioeconomic status or parental education, frequently account for little to no variance in human characteristics.

Findings from behavioral genetic research into human intelligence indicate that intelligence is heavily influenced by genetic factors. Estimates of the heritability of intelligence generally range between 60% and 80%, with some studies finding that intelligence is almost 100% heritable. Estimates derived from twins separated at birth and reared apart also have detected very high levels of genetic influence, usually above 70%. Conversely, shared environmental influences usually show little to no influence.

The relative contributions of environmental and genetic factors to intelligence, however, vary by age. In infancy and early childhood, estimates of heritability rarely exceed 40%, and test–retest reliabilities range from low to moderate. Estimates of common environmental effects range from 20% to 30%, on average. Unique environmental influences account for the rest of the variance in IQ early in life. This pattern reverses, however, by age 12, when genetic influences become dominant, environmental influences decline substantially, and test–retest reliabilities remain remarkably strong and consistent over time.

Estimates of heritability do not provide any information regarding which genes are associated with IQ. Recent research, however, has helped to fill in this void. Neuroscientific findings, usually based on complex brain imaging scans, have shown that IQ is moderately associated with brain size, is strongly associated with the overall number of cortical neurons, is strongly associated with the volume of grey matter in the frontal cortex of the brain, and is associated with neuronal conduction velocity (i.e., the efficiency of the neurons in transporting messages; see Ellis & Walsh, 2003). These biological functions are primarily under genetic control. Because of this, many scholars now argue that the reason IQ is highly heritable is because genes are inherited that control these basic neurological functions.

On the other hand, environmental influences on IQ are notoriously difficult to detect, because the genes associated with cognition are also associated with social behaviors. Parents who read regularly, for example, are likely to have more books in their home and to have children with above-average IQs (Ellis & Walsh, 2003). This correlation has led many social scientists to erroneously conclude that the number of books in a home positively influences a child's IQ. This conclusion is erroneous, because the correlations among parental reading, the number of books in the home, and the IQ of the child involve both genetic and environmental influences. High-IQ parents are more likely to read and hence to have more books in their home than are low-IQ parents. Once shared genetic influences are taken into account, scientists find frequently that socialization influences, such as parenting, appear unrelated to individual IQ. Indeed, planned interventions designed to permanently increase IQ, such as Head Start, have typically failed to produce lasting results (Ellis & Walsh, 2003).

Although it is fair to say that IQ likely cannot be increased, it is equally fair to say that IQ can be reduced. Evidence shows that the behavior of pregnant women can negatively influence the development of the fetus. Insults to the developing central nervous system from maternal drug and alcohol use, smoking, and high levels of stress hormones are associated with compromised neurological development and reduced IQ. Birth complications, such as oxygen deprivation and toxemia, have been found to reduce IQ. Moreover, environmental insults after birth can also occur when young children ingest lead and other

heavy metals, when they sustain brain damage due to accidents or abuse, or when they are severely neglected.

IQ Differences Between Criminal and Noncriminal Groups

The majority of studies have found IQ differences between offenders and nonoffenders (e.g., Ellis & Walsh, 2003). On average, the IQ for chronic juvenile offenders is 92, about half a standard deviation below the population mean. For chronic adult offenders, however, the average IQ is 85, 1 standard deviation below the population mean. A study of Texas inmates who entered the prison system in 2002 indicated that approximately 23% of the inmates scored below 80, almost 69% scored between 80 and 109, and only 9.6% scored above 110 (Ellis & Walsh, 2003).

To give readers an understanding of the relative proportions of individuals with IQs in those ranges, we offer the following statistics, from Ellis and Walsh (2003): Only 9.18% of individuals in the general population score at or below 80, 63.39% have an IQ between 80 and 109, and 25% have an IQ at or above 110. These data clearly show that low-IQ offenders (below 80) are substantially overrepresented in the Texas prison population (23%–9.18%), that those with scores between 80 and 109 are modestly overrepresented compared with the nonincarcerated population (69%–63%), and that individuals with IQ scores at or above 110 are underrepresented in the Texas prison population (9.6%–25%). Data from every other state reveal the same pattern.

IQ scores derived from prison inmates depict a clear relationship between IQ and offending; however, it is important to note that some scholars question the validity of this association. They question whether criminal justice processes function so that intellectually dull offenders are more likely to be incarcerated. If so, the association between IQ and imprisonment would be substantially inflated. Data from nonincarcerated offenders, usually matched on criminal record, cast doubt on this criticism. Studies have found that low-IQ offenders are more likely to be involved in crime over their life course, that they are more likely to be involved in chronic property crime, and that they are more likely to commit acts of violence (Ellis & Walsh, 2003). Their overinvolvement in crime, especially crimes involving violence, account for the reasons why they are incarcerated, not their low IQ.

Even so, it is important to point out that when data are collected through self-report questionnaires, whereby respondents are asked questions about their involvement in a range of criminal and delinquent acts, the magnitude of the association between IQ and criminal/delinquent involvement diminishes (Ellis & Walsh, 2003). Whereas some scholars point to this empirical regularity as evidence of the limited explanatory power of IQ, others correctly observe that the types of behaviors being measured

influence the IQ → delinquency association. For example, it is relatively common for adolescents to cheat on tests or to stay out later than their parent-imposed curfews. The majority of adolescents self-report involvement in these types of relatively innocuous behaviors. Because these behaviors are very common (some would argue normal), adolescents from all IQ ranges are equally likely to cheat or to violate their curfews.

This should not be taken as evidence that IQ is unimportant in delinquency or criminal behavior. When researchers examine self-report data that are based on measures of relatively serious crime, such as armed robbery, burglary, or assault, they note substantial IQ differences. Individuals with relatively lower IQs are more likely to report engaging in these serious criminal acts. The association between IQ and misbehavior therefore depends on the seriousness of the behavior being analyzed, with the association becoming stronger as the behavior becomes more serious.

The strength of the IQ → crime association also depends on how frequently the individual engages in criminal and delinquent behavior. Low-IQ individuals are more likely to engage in serious misbehavior more frequently than their higher IQ counterparts, and they are more likely to engage in serious misbehavior over a longer span of their life course. Most life-course-persistent offenders also score relatively low on tests of IQ.

Another important aspect of the IQ → crime association has to do with the difference between *performance IQ* and *verbal IQ*. Verbal IQ reflects an individual's ability to read and comprehend written material and to use words correctly. Performance IQ is assessed through measures of spatial visualization, pattern recognition, and object assembly. Research has consistently shown that offenders are more likely to score lower on measures of verbal IQ than on measures of performance IQ. Explanations for this pattern are in short supply, but the association likely has to do with deficits in the language centers of the brain, specifically, Wernicke's and Broca's areas, that are indirectly assessed by the IQ test.

Language skills and abilities are crucial for healthy human development and appear universal to humans. For this reason, many linguists view language ability as innate, with the neuronal structures necessary for the development, use, and comprehension of language embedded in our DNA. Indeed, so strong is the "language instinct" that, barring any biological or genetic insult, all humans will develop the use of a language.

The use of language allows individuals to discuss problems and negotiate conflict. It allows for the use of instructions in learning, and it allows for feedback, teaching, and training. Reading comprehension, moreover, gives one the ability to learn from outside sources and to understand complexity in day-to-day encounters.

Language abilities emerge early in the life course, with verbal deficits identifiable by age 3. Unfortunately,

language abilities become resistant to change by about age 9 or 10, when the language centers of the brain appear to formalize. These abilities are highly heritable, so whereas approximately 80% to 85% of the words an individual has in his or her vocabulary overlap with his or her parents' vocabulary, the architecture that allows for these abilities appears to be genetic.

Verbal IQ also correlates moderately with the ability to think abstractly. Individuals capable of abstract thinking tend to be able to see the nuances in situations and relationships. They better understand not only the simple but also the complex. They see the interconnections between their attitudes and behaviors and the consequences that flow from their beliefs and behaviors. More important, they can understand how their behaviors and attitudes affect and influence others. Criminals, research tells us, tend to be concrete in their thinking—that is, they view the world in simplistic ways, often much like that of a young child (Ellis & Walsh, 2003). They are strongly influenced by the here and now, they do not tend to make effective generalizations from one situation to the next, and they tend to be very literal in their understanding of life events.

Criticism of the IQ → Crime Relationship

Although much of the research shows that there is a modest to strong relationship between intelligence and antisocial behavior, some researchers dispute the validity of this relationship. Critics argue that the empirical association between intelligence and criminal behavior may be accounted for by other factors. They highlight three general criticisms: (1) that differences in police detection ultimately account for the IQ → crime relationship; (2) that an individual's race and/or class may account for the relationship; and (3) that the relationship is in the opposite direction, namely, that it is antisocial behavior that leads to lower intelligence. We now examine each of these arguments in greater detail.

First, the *differential detection hypothesis* states, in essence, that criminals with lower intelligence are more likely to be detected by the police for their unlawful actions compared with criminals with higher intelligence. In other words, individuals with higher intelligence may be committing crimes at the same rate as individuals with lower intelligence, but only the less intelligent ones are getting caught by the police. For that reason, it is argued that studies that show a relationship between intelligence and criminal behavior are invalid because the more intelligent criminals are able to avoid being detected by the police.

Research does not support this criticism. Several studies have compared mean IQ scores of delinquents detected by the police and delinquents not detected by the police, primarily through the use of self-reported questionnaires (e.g., Ellis & Walsh, 2003). These studies have found no

significant differences in IQ levels between individuals caught by the police and those not captured by the police. In all the studies, delinquents, arrested or not, scored significantly lower on intelligence compared with non-delinquents. Overall, converging evidence rejects the differential detection hypothesis.

The second counterhypothesis against the intelligence → crime relationship stems from a traditional sociological perspective. Sociologists are not usually concerned with explaining individual differences in behavior, because they believe that people who are exposed to the same environment will respond in a similar way. Thus, it is not surprising that many sociologists discount the relationship between intelligence and criminal behavior in favor of a *race and/or class hypothesis*. Most sociologists view IQ test scores as a proxy for race and class and not a true measure of intelligence. Higher scores on intelligence tests, they argue, reflect how well an individual has assimilated and internalized white, middle-class values instead of a valid assessment of intellectual ability.

To assess the validity of this argument, researchers include measures of race, class, and intelligence in their analyses to determine whether intelligence remains related to crime after controlling for these other factors. These studies have shown that the relationship between intelligence and crime remains even after the influence of race and class has been accounted for (Ellis & Walsh, 2003). Moreover, in every assessment of intelligence, African Americans score lower than whites or Asians. Across thousands of studies, the IQ for African Americans averages 85, whereas whites average 102 and Asians average 105. No study that has examined racial differences in IQ has been able to account for these differences.

The third argument that questions the relationship between intelligence and criminal behavior focuses on the chronological order of these two factors. Whereas the relationship between intelligence and crime assumes that individuals with lower intelligence are more likely to engage in criminal activity, critics argue that this relationship may in fact be temporally reversed. Instead of intelligence influencing criminal behavior, they maintain, it may be that criminal behavior affects an individual's level of intelligence. There are two main hypotheses related to this perspective. The first is called the *temporal order hypothesis*: Some scholars hypothesize that a delinquent lifestyle can result in lower intellectual functioning. For example, an individual can suffer from head injuries as a result of physical violence, or he or she can experience the erosion of cognitive abilities through prolonged substance abuse. In essence, it is the individual's criminal lifestyle that is to blame for his or her limited intellectual abilities, not the other way around.

The problem with this argument, however, is that ample evidence has shown that intelligence is established well before the onset of serious delinquency. In any case, a suitable way for researchers to examine this argument is

by sampling younger children in an attempt to decrease the possibility that they have already experienced the negative consequences of drug abuse and violence. These studies, along with those that demonstrate that intelligence is established early in life, cast suspicion on the delinquent lifestyle interpretation of the intelligence → crime relationship.

The second argument stemming from the temporal order hypothesis states that delinquents are simply not motivated to do well on intelligence tests; specifically, anti-social adolescents may lack motivation for or interest in completing an intelligence test. Therefore, although it appears that criminals are scoring lower on intelligence tests, the lower scores are in fact the result of their lack of motivation to complete the test instead of a true reflection of their intellectual abilities. To address this issue, researchers have used a variety of methods to control for levels of motivation. Indeed, when controlling for these motivational issues, the relationship between intelligence and crime remains.

Indirect Relationships

Research has consistently shown that delinquents score, on average, 8 percentage points lower on IQ tests than non-delinquents. As a result, criminologists began investigating the mechanisms by which intelligence influences criminal behavior. Little evidence emerged, however, to suggest that the relationship between intelligence and delinquency was purely direct. For that reason, criminologists shifted their attention toward examining the possible indirect effects relating intelligence to criminal behavior. Studies have revealed that school performance is an important mediating factor (Ellis & Walsh, 2003). Individuals with lower intelligence are more likely to struggle in their academic endeavors, which may then increase their likelihood of delinquent involvement. After school performance emerged as an important factor in explaining the intelligence → crime relationship, the next step was to determine the specific mechanism by which school performance exerts its effects on delinquency. Research soon revealed that an individual's attitude toward school was a substantive predictor of school performance (Ellis & Walsh, 2003). Simply put, intelligence predicts school performance, which affects an individual's attitude toward school, which then influences delinquent involvement; specifically, adequate school performance is frequently associated with a good attitude about school, and poor school performance frequently results in a poor attitude.

Many criminologists attempt to explain the indirect relationship between intelligence and crime from a *social bond* perspective. The core premise of social bond theory states that individuals are born with the innate ability to commit crime; therefore, people need to be stopped from acting on these innate and selfish antisocial desires. The

inhibition to commit crime is accomplished when an individual forms a strong bond to society. There are four social bonds that tie individuals to society: (1) attachment, (2) commitment, (3) involvement, and (4) belief.

Of these four bonds, two—commitment to school and attachment to school—are especially relevant in explaining the indirect relationship between intelligence and crime. *Attachment* is the degree to which an individual has close bonds with other individuals (e.g., teachers). This bond is believed to help restrain the adolescent from committing crimes. In theory, a student with a strong attachment to a teacher will try to avoid causing disappointment and will thus steer clear from acting out delinquently. However, when an individual's intellectual ability interferes with his or her ability to succeed in school, his or her frustration level may increase and subsequently weaken his or her attachment to school officials.

Commitment refers to an individual's level of dedication to prosocial activities, such as school. For example, an adolescent who is heavily involved in school will have more to lose by committing crime, not to mention simply less time to think about and commit crimes, compared with an individual who is not as committed to his or her education. However, if an individual's intellectual ability is limited, then success in school may suffer, and the student may be less likely to maintain a strong commitment to his or her education.

Intelligence and Interventions

We stated earlier that no known social intervention has successfully increased IQ scores over the life course. Programs designed to increase IQ and thus reduce crime and violence are likely to fail. Even so, this should not be taken as evidence that cognitive interventions in general are likely to fail. Indeed, quite the opposite is true: Programs that reduce criminal involvement and violence are more likely to use principles of cognitive therapy and behavioral modeling.

IQ appears to be immutable after childhood, but individuals, even those with low IQs, can be instructed to recognize criminal thinking patterns and to alter those patterns. Evidence indicates that IQ is not as important as the way individuals reason, the moral values they hold, or even their level of impulsivity. Because of this, interventions that occur early or later in the life span can be effective in reducing delinquency and crime even if they do not increase one's IQ.

One effective early intervention program is the Perry Preschool Project, which offers children from lower socioeconomic status with IQ scores in the range of 60 to 88 the opportunity to receive 2 years of intensive preschool education. The results obtained from this project revealed that children who received these 2 years of preschool had fewer arrests and were more likely to be employed during

adolescence (vs. youth with the same IQ and who did not attend preschool; Ellis & Walsh, 2003). Although IQ was impacted by the program, educational achievement was and remained the most important factor related to future delinquency.

One of the goals of the U.S. correctional system is to keep criminals from returning to prison once they have been released. Many rehabilitative programs have been implemented to help achieve this goal. Research has consistently indicated that the most effective programs for incarcerated individuals are those that target and change thinking styles and that use behavioral modification techniques (Ellis & Walsh, 2003). These programs are effective in part because they target known, changeable individual factors and they do so at a level the offender can understand. Cognitive behavioral programs attempt to change what offenders think, and they try to alter the behavior of offenders through positive and negative reinforcements.

It is also instructive that psychodynamic treatment modalities have not been proven effective with the criminal population. Scholars believe that psychodynamic programs are mismatched to the average offender's IQ level. Psychodynamic treatment is effective for individuals with average to above-average IQs, but it is not effective for below-average-IQ individuals.

Although it is important to focus on particular risk factors that place an individual at a higher likelihood of recommitting crimes, such as cognitive styles, other characteristics specific to the individual should also be considered. These characteristics, often referred to as *responsivity factors*, need to be identified because they have the potential to interfere with an individual's ability to succeed in a treatment program. There are several responsivity factors to consider, such as personality disorders; attention deficit disorder; child care problems; transportation needs; and, most important to this discussion, intelligence.

An offender's intelligence level should be considered before he or she is placed into a correctional treatment program. For example, very-low-functioning offenders will have a difficult time succeeding in treatment programs that require written homework or abstract thinking. Placing intellectually limited offenders into rehabilitation programs that require at least an average intelligence may waste resources and increase the likelihood of the person failing the program or returning to prison.

Conclusion

The relationship between intelligence and crime remains a fiercely debated topic. Despite recent advancements through revised intelligence tests and sophisticated brain imaging techniques, there remain numerous theoretical deficiencies regarding the mechanisms underlying the intelligence → crime relationship. Needless to say, these shortcomings need to be examined more thoroughly, and

new hypotheses must emerge, before the role of intelligence in criminal behavior can be fully explained. True understanding may eventually emerge with the unification of several perspectives from various disciplines; therefore, one cannot forget that intelligence may just be one small piece of a larger puzzle in which numerous variables taken together can best explain the cognitive makeup of today's modern criminal.

MENTAL ILLNESS AND CRIME

SCOTT BLOUGH

Tiffin University

Crime and disorder are often associated with deviation from the traditional norms and values of society. To ensure that the norms and values are met and respected, laws are instituted that govern behaviors of individuals and prohibit deviant behaviors. These deviant behaviors are often associated with crime. According to the U.S. Surgeon General, the term *mental illness* refers collectively to all diagnosable mental disorders: conditions that result in alterations of thinking, mood, and behavior. These alterations often cause deviations from normal behavior and thus are often classified as crime. Couple this with the estimated 5% of the U.S. population that have a mental illness, and the problem of mental illness and crime becomes apparent.

Individuals with mental illness typically access the criminal justice system through law enforcement, courts, and corrections (jail, prison, community corrections, and probation). At the time of arrest, mentally ill offenders begin the journey through the criminal justice system. This flow through the system comprises the following five steps: (1) arrest; (2) booking (jail); (3) court; (4) prison, jail, or probation; and (5) release.

During each of these phases, mentally ill offenders come into contact with different actors in the criminal justice system, ranging from law enforcement officers, prosecutors and defense attorneys, through judicial personnel to corrections personnel. As a result, according to the Bazelon Center for Mental Health Law (<http://www.bazelon.org>), these

offenders repeatedly use a significant amount of law enforcement and judicial resources during their initial contact. Also, these offenders' lack of conformity to correctional policy often leads to significantly more time spent in the institutions or on probation, further draining already-scarce resources.

History

To fully appreciate the impact of mental illness and crime, it is important to understand the dynamics of the population of which we speak. In 1955, there were 558,239 severely mentally ill patients in U.S. public psychiatric hospitals; in 1994, there were 71,619. On the basis of population growth, at the same per capita utilization as in 1955, there would have been an estimated 885,010 patients in state hospitals in 1994 (Torrey, 1997). Most of this projected population—more than 800,000 potential patients—live in the community.

The treatment of individuals with mental illness has undergone vast shifts over time. Around 400 BCE, the Greek physician Hippocrates treated mental illness as a physiological disease. Other cultures, including Indian, Egyptian, and Roman, understood mental illness to be a result of displeasure from the gods or some form of demonic possession (MacLowry & Samuels, 2003). Throughout the Middle Ages, many mentally ill people

were assumed to be witches or possessed by demons. In 1407, the first European establishment specifically for people with mental illness was established in Valencia, Spain (MacLowry & Samuels, 2003). During the 1600s, mentally ill people were confined in dungeons and mixed with handicapped people, vagrants, and delinquents, while experiencing increasingly inhumane treatment. In the 1700s, several European reformers began to slowly change the way mentally ill people were treated. In particular, the Gaol Act of 1774, promoted by John Howard, the High Sheriff of Bedford, addressed the idea of improving jails. Among other things, Howard published *The State of Prisons in England and Wales, with an Account of Some Foreign Prisons* in 1777, which was an account of his travels and *gaol* (jail) inspections across England. His work was so controversial that it was banned in several foreign countries, one of which was France. In his book, Howard advocated for the removal of mentally ill inmates from gaols and their placement in institutions designed for their care.

In addition to Howard's work in England, the United States had its share of corrections reformers. Thomas Jefferson worked with Benjamin LaTrobe in Virginia to develop a circular prison that provided direct viewing of inmates by the guards. The prison was completed in 1800 and aptly named the Virginia State Penitentiary. Among continuing reforms, such as the separation of males and females (1789) and the separation of juveniles from adults (1823), the separation of mentally ill people from inmates in prisons and jails and their placement in mental institutions occurred in 1854. This was largely due to the work of Dorothea Dix during the 1840s. Living in Massachusetts, she observed mentally ill people of all ages incarcerated with criminals. These individuals were often left unclothed and in dark cells that lacked both heat and bathroom facilities. In addition, many of the mentally ill were chained and beaten on a regular basis. Armed with that information, Dix successfully lobbied for and established 32 state hospitals for the mentally ill over a 40-year period in the mid- to late 1800s (MacLowry & Samuels, 2003). In addition to these reforms, in 1887 a female journalist named Nellie Bly went undercover in Blackwell Island, a New York facility for mentally ill women. Her undercover investigation, sponsored by the *New York World* newspaper, uncovered widespread mistreatment of patients and corruption of staff throughout the facility. Among the issues she uncovered were poor hygiene practices (with multiple patients using the same towel and comb), food quality issues (patients were fed rancid food and doctors and nurses dined on fresh fruit, bread, and meat), and medical malpractice (patients were rarely seen by doctors). As a result of Bly's exposé, an investigation commenced that resulted in some officials being tried in court and fired, as well as a \$3 million allocation for improvements at the facility (see http://americanhistory.suite101.com/article.cfm/nellie_bly_stunt_reporter).

This system was in place for more than 100 years before the deinstitutionalization of the mentally ill, brought about by horrible abuses and lack of accountability in mental institutions, gained momentum. This momentum would carry the mentally ill back into prisons and jails at an alarming rate and make America's jails and prisons, in essence, warehouses for mentally ill individuals.

During the 1960s, many mentally ill people were removed from institutions and moved toward community placement and local mental health care. In 1963, Congress passed the Mental Retardation Facilities and Community Mental Health Centers Construction Act, which provided federal monies to develop a network of community-based mental health resources that would lessen the burden on the institutions. This legislation presumed that mentally ill individuals would voluntarily seek out assistance and treatment. Unfortunately, this presumption was not correct.

The deinstitutionalization of the mentally ill and the issues faced by communities in regard to lack of treatment and resources resulted in the formation of several advocacy organizations, the most prolific of which is the National Alliance on Mental Illness (NAMI). According to the group's Web site (<http://www.nami.org>), NAMI is "the nation's largest grassroots organization for people with mental illness and their families. Founded in 1979, NAMI has affiliates in every state and in more than 1,100 local communities across the country." Among many other functions, NAMI formed an advocacy center called the Law and Criminal Justice Action Center, which is responsible for promoting the interests of people with mental illness in state and federal legislation. NAMI and other advocacy groups have advanced awareness and treatment of mentally ill people in the justice system.

As deinstitutionalization became the norm in the United States, there took place an influx of mentally ill persons into communities that were ill-prepared to care for them. As a result of this influx and the lack of preparedness, communities often turned to the system of last resort: the criminal justice system, which comprises law enforcement, courts, and corrections. Law enforcement and corrections operate 24 hours a day, 7 days a week, thus making them the logical choice for communities experiencing issues with mentally ill people. As a result, many mentally ill people went from state institutions to state and local prisons and jails by way of law enforcement arrest and court convictions.

Police and the Mentally Ill

To understand this phenomenon, it is important to explain the process by which many mentally ill people were ultimately imprisoned. After being placed under community supervision, many persons with mental illness were left to their own devices for obtaining and properly taking their prescribed medication. One of the major assumptions that

policymakers made during the transition was that, with better medication for mental illness, mentally ill persons would be medication compliant. This assumption proved to be false; people with mental illness often failed to comply with their medication and then violated the law or some social precedent. This violation often resulted in the commission of a crime or homelessness. Many of the severely mentally ill people who were released into the community through deinstitutionalization are now part of the 600,000 people in America who are homeless. Of these, it is believed that at least one third are mentally ill (U.S. Department of Health and Human Services, 1999). The most common offenses committed by mentally ill persons are assault, theft, robbery, shoplifting, alcohol or drug-related charges, and trespassing (Robertson, Pearson, & Gibb, 1996). Thus, law enforcement has played a major role in responding to and resolving these issues.

A study conducted by the Consensus Project and published in 2002 (Council of State Governments, 2002) indicated that in “police departments of U.S. cities with a population greater than 100,000, approximately 7 percent of all police contacts, both investigations and complaints, involved a person believed to have a mental illness” (p. 21). Further exemplifying the problem, the study also made the following observation:

During the year 2000, law enforcement officers in Florida transported more than 40,000 people with mental illness for involuntary 72 hour psychiatric examinations under the Baker Act. This exceeds the number of arrests in the state during 2000 for either aggravated assault (39,120) or burglary (26,087). (p. 25)

In 1998, New York City police officers transported 24,787 emotionally disturbed persons to hospitals for psychiatric evaluations, up from 1,000 in 1976 (Bumiller, 1999). Law enforcement officers’ safety is compromised when they are handling incidents involving mentally ill offenders. In 1998, mentally ill offenders killed law enforcement officers at a rate 5.5 times greater than that of the rest of the population (<http://www.psychlaws.org>). These facts make it apparent that law enforcement is the initial point of governmental contact that mentally ill offenders will have.

To more effectively handle the increased contact between law enforcement personnel and mentally ill people, U.S. law enforcement agencies have implemented numerous programs. The most effective are training programs designed to equip officers with the resources needed to effectively and appropriately deal with the mentally ill. Among these programs is the Crisis Intervention Team (CIT), one of the most successful. Originating in Memphis, Tennessee, in 1988, it is often referred to as the *Memphis Model*. According to Dr. Mark Munetz (personal communication, February 1, 2008),

The first CIT program began in Memphis, Tennessee. In 1987, 27-year-old Joseph Dewayne Robinson was shot and killed during an incident with the Memphis Police Department. This shooting outraged the community. From this community crisis

emerged in 1988 a new way of doing business for both the police and the mental health community in Memphis, based on a collaborative effort designed to help police officers identify and deal with mentally ill people.

The premise of the CIT program is to improve law enforcement officers’ response to the mentally ill. It is a law enforcement–based specialized response model. Until the CIT was developed, most basic law enforcement training referred to mentally ill individuals as *emotionally disturbed people* (EDP for short) and gave very basic instruction on the dangers officers face when encountering such individuals. This instruction ranged from describing the mentally ill as unpredictable to delineations of the proper distance an officer should maintain from such an individual. There was no training on how to effectively deescalate a situation involving a mentally ill offender. Thus, the 1987 Memphis case just described was often the norm rather than the exception. As CIT programs have become more widespread, these incidents have declined in number.

The CIT program relies on 10 elements to allow law enforcement officers to effectively and efficiently deal with mentally ill offenders (Schwarzfeld, Reuland, & Plotkin, 2008). As with any multidimensional program, collaboration plays a very important part. The CIT program relies on ensuring the appropriate response from incident inception to incident disposition and thus involves all components of law enforcement. The following is a list of the 10 components Schwarzfeld et al. (2008) recommended:

1. Collaborative Planning and Implementation
2. Program Design
3. Specialized Training
4. Call-Taker and Dispatcher Protocols
5. Stabilization, Observation, and Disposition
6. Transportation and Custodial Transfer
7. Information Exchange and Confidentiality
8. Treatment, Supports, and Services
9. Organizational Support
10. Program Evaluation and Sustainability

The key to a successful CIT program is the collaboration among agencies involved with law enforcement; health care; mental health; corrections; courts; advocacy groups; and, perhaps most important, funding agencies and sources. Another key component is providing first responders—both dispatchers and law enforcement officers—with specialized training. That training typically includes subjects such as mental illnesses, signs and symptoms of mental illnesses, de-escalation techniques, stabilization, disposition options, community resources, and legal issues. The most important part of the program is the focus on proper identification, intervention, and referral to the appropriate community resources.

The CIT program in Memphis provides 40 hours of specialized training for law enforcement officers, encompassing much of the aforementioned information. According to

Dupont, Cochran, and Bush, (1999), the Memphis CIT program reduced officer injuries sustained during mental disturbance calls by over 80%. The Memphis CIT program has also proven to be very cost-effective in that it has reduced the number of rearrests among mentally ill offenders. In addition, officers trained in the CIT program are 25% more likely to transport mentally ill offenders to a psychiatric or community mental health facility instead of to jail (Teller, Munetz, Gil, & Ritter, 2006).

The CIT program is one of the most effective means of helping law enforcement personnel effectively handle persons with mental illness. According to the Bureau of Justice Statistics (2006), there are more than 400 CIT programs operating in the United States. The CIT program has been successful in both metropolitan and rural areas as well.

Courts and the Mentally Ill

After initial contact with law enforcement, mentally ill offenders who are arrested are booked into jail and receive an initial hearing in a court, where they often lack the proper resources, both mental and financial, to ensure proper outcomes. A 2002 study conducted by the Council of State and Local Governments: Criminal Justice/Mental Health Consensus Project determined that “People with mental illness are falling through the cracks of this country’s social safety net and are landing in the criminal justice system at an alarming rate” (p. 2). The report also focused on the fact that many individuals with mental illness are turned away or intimidated by the mental health system; thus, “Officials in the criminal justice system have encountered people with mental illness with increasing frequency” (p. 3).

Part of the reason why mentally ill individuals are falling through the cracks is funding. Mental health agencies are mandated to provide care to persons designated as mentally ill by state governments. These agencies are given funding to supplement the expense of treatment and care for those individuals, often referred to as *clients*. A gap in the funding system exists when the client enters the criminal justice system. The funding stream for a client who enters the criminal justice system changes from the mental health agency to the criminal justice agency. This change often interrupts the continuity of care for the client and results in a reevaluation of the client’s needs by criminal justice agency personnel without the benefit of medical and mental health records from the mental health agency. To combat this recurring issue, *mental health courts* were created. A report by the Council of State Governments (2008) provided the following definition of mental health courts:

A mental health court is a specialized court docket for certain defendants with mental illnesses that substitutes a problem-solving model for traditional criminal court processing. Participants are identified through mental health screening and assessments and voluntarily participate in a judicially supervised treatment plan developed jointly by a team of court

staff and mental health professionals. Incentives reward adherence to the treatment plan or other court conditions, non-adherence may be sanctioned, and success or graduation is defined according to predetermined criteria. (p. 30)

Only a handful of mental health courts were implemented in the late 1990s, but today more than 175 are now functioning nationwide (<http://www.cjmh-infonet.org>). It is interesting to note that mental health courts are not cookie-cutter projects; they vary in size, scope, programs, and partnerships, making them unique to the communities and populations they serve. The framework and utility of the mental health courts provide offenders with an opportunity to participate in court-supervised treatment. This treatment involves a team composed of a judge, court personnel, and treatment and community providers, all of whom define the terms of participation. Throughout the case, continuous assessments are provided to the treatment team, along with individualized sanctions and incentives for the offender. The final key element is the resolution of the case upon successful completion of the mandated treatment plan (Council of State Governments, 2008).

Among other goals, such as increased public safety, mental health courts seek to provide improved quality of life for participants by ensuring that program participants are connected to needed community-based treatments, housing, and other services that encourage recovery. On a broader scale, they seek to find a more effective use of resources for sponsoring jurisdictions by reducing repeated contacts between mentally ill people and the criminal justice system and by providing, when appropriate, treatment in the community, where it is more effective and less costly than in correctional institutions (Council of State Governments, 2008).

Several studies have evaluated the effectiveness of mental health courts. Moore and Hiday (2006) found that participants were significantly less likely to incur new charges than a comparison group of offenders with mental illness who did not utilize the mental health court. In addition to fewer new charges, participants in the Broward County Mental Health Court spent less time in jail than offenders going through traditional criminal court (Boothroyd, Poythress, McGaha, & Petrila, 2003). This is significant, because mentally ill inmates are typically incarcerated for up to three times longer than typical inmates. By minimizing mentally ill inmates’ jail time, the criminal justice system may experience significant cost savings in the long term. The cost of implementing a mental health court is not a significant burden for government. This was verified in a case study completed by the RAND Corporation in 2007 that assessed the Allegheny County Mental Health Court in Pennsylvania (Ridgely et al., 2007). The study found that the program did not result in substantial added costs, at least in the short term, over traditional court processing for individuals with serious mental illnesses. In addition, it suggested that the mental health court may result in a net savings for government over the long term because of decreased recidivism and use of the criminal justice system’s resources.

Seminal Court Cases

In addition to involvement in the initial and subsequent appearances of mentally ill offenders, the courts have been active in clarifying the rights of mentally ill inmates over the past several decades. Prior to this, the courts operated under the “hands-off” doctrine, which allowed prisons and jails in the United States to operate in relative obscurity. During this time, before the 1960s, the courts held the belief that correctional administrators were better equipped than the judicial system to govern the operation of prisons and jails. As the civil rights movement advanced, courts began to take a more detailed look at inmate complaints, resulting in court intervention under the auspices of inmates’ constitutional rights.

The courts have had a significant impact on the treatment of mentally ill offenders in prisons and jails as well as on the “right to treatment for people with mental illnesses” (Perez, Liefman, & Estrada, 2003). This right was first recognized in the 1972 case of *Wyatt v. Stickney* at a district court in Alabama. In this decision, the court concluded that there were many treatment options for individuals with mental illness that did not involve warehousing in large state institutions. The court found specifically that institutionalization of the mentally ill did not guarantee “the constitutional right to receive such individual treatment as will give each individual with mental illness a realistic opportunity to be cured or to improve his or her mental condition” (at 785, *Wyatt v. Stickney*). This effectively placed the burden of treatment of the mentally ill on community-based behavioral health centers, of which few existed because of the previous focus on institutionalization. Thus, the goal of reintegration of mentally ill persons into the community was introduced.

According to Perez et al. (2003), many states “saw deinstitutionalization as an opportunity to save money rather than an opportunity to improve their mental health services” (p. 63). This lack of planning and disregard for the deinstitutionalized individuals led to a dramatic increase in homelessness and incarceration. Perez et al. also made the following observation: “Ironically, instead of deinstitutionalization, we have witnessed the reinstitutionalization of individuals with mental illnesses from deplorable state psychiatric hospitals to correctional institutions, where conditions are often worse” (p. 63).

Just as the courts first began the deinstitutionalization movement in 1972, they began to become more active in prisoner rights issues. One of the key cases related to health care came out of the U.S. Supreme Court in 1976. Although not specifically geared toward mentally ill inmates, it is still considered a landmark case. This case is *Estelle v. Gamble*, and it had several implications for jails and prisons in the United States:

- It guaranteed prison (jail) inmates medical treatment.
- It established the “deliberate indifference” standards.

- It deemed a lack of medical treatment “cruel and unusual punishment” (Eighth Amendment).
- It stated that the Fourteenth Amendment made the preceding three items applicable to states.

The court considered three issues when discussing “deliberate indifference”:

1. The amenability of the patient’s condition to treatment
2. The consequences to the patient if treatment does not occur
3. The likelihood of a favorable outcome

Deliberate indifference constitutes the “unnecessary and wanton infliction of pain” proscribed by the Eighth Amendment:

Whether the indifference is manifested by prison doctors in their response to the prisoner’s needs or by prison guards in intentionally denying or delaying access to medical care or intentionally interfering with the treatment once prescribed. Regardless of how evidenced, deliberate indifference to a prisoner’s serious illness or injury states a cause of action. (*Estelle v. Gamble*, 1976, pp. 104–105)

The courts are not in the business of second-guessing health care providers or treatment prescriptions but instead seek to achieve the following:

[To] ensure that decisions concerning the nature and timing of medical care are made by medical personnel, using equipment designed for medical use, in locations conducive to medical functions, and for reasons that are purely medical. (Neisser, 1977, pp. 956–957)

The courts have also weighed in on treatment issues within correctional facilities. *Ruiz v. Estelle* (1980) is the seminal case that established widely accepted standards for an adequate prison mental health system. In the Ruiz case, the court held that the Constitution requires the following:

- A systemic program for screening and evaluating inmates in order to identify those who require mental health treatment
- Treatment that entails more than segregation and close supervision of the inmate patients
- The participation of trained mental health professionals, who must be employed in sufficient numbers to identify and treat in an individualized manner those treatable inmates who have serious mental disorders
- Accurate, complete, and confidential records of the mental health treatment process
- A basic program for the identification, treatment, and supervision of inmates with suicidal tendencies

The court also stated that prescription and administration of behavior-altering medications in dangerous amounts, by dangerous methods, or without appropriate supervision

and periodic evaluation is an unacceptable method of treatment.

Even though *Ruiz v. Estelle* was decided in 1980, it was not until the mid-1990s that prisoner mental health treatment received national attention once again. First, in 1993, the case of *Casey v. Lewis* was brought by female inmates in the Arizona prison system. The court found that the Arizona prison officials were deliberately indifferent to the serious medical needs of female inmates because they did not provide facilities and mental health care services for females that were comparable to those provided to males. The court found that this was a violation of the Eighth Amendment. In its decision, the court cited the following problems:

- Inadequate screening of incoming inmates. For women, unqualified security staff made the decision as to which women were mentally ill.
- Records of all inmates were not routinely reviewed, and mentally ill inmates did not receive help until they asked for it or their condition deteriorated.
- Inadequate staffing of psychiatrists and psychologists.
- Delays in assessment and treatment.
- Use of lockdown as an alternative to mental health care; the court characterized this as “appalling.”
- Problems with monitoring of, and delays in receipt of, psychotropic medication. Medication was prescribed, continued, and discontinued without face-to-face evaluations by psychiatrists. Also, there was no method to ensure that patients take their medication.
- Insufficient mental health programming.
- Behavior modification implemented by untrained security officers.

Casey v. Lewis brought to light the use of “unqualified security staff” in screening and the implementation of behavioral modification techniques for mentally ill inmates. As a result, the court determined that mental health screening and mental health treatment should be provided by “qualified mental health personnel,” defined by Blough (2004) as “physicians, psychiatrists, psychologists, physician assistants, nurses, psychiatric social workers, and others who by virtue of their education, credentials and experience are permitted by law to evaluate and care for the mental health needs of prisoners” (p. 5). Following on the heels of *Casey v. Lewis*, in 1995 Ohio became the center of attention for inmates with mental illness in prisons.

Dunn v. Voinovich (1995) was a comprehensive class action suit that challenged the mental health care practices of the Ohio Department of Rehabilitation and Corrections. According to the decision, the “Dunn Decree” mandated the following:

- That mental health services be provided “within the framework of a community health model” and in the “least restrictive available environment and by the least intrusive measures available” (*Dunn v. Voinovich*, p. 4).

- Implementation of a three-tiered system of services: (1) inpatient hospital beds for long-term care, (2) residential treatment beds and crisis beds for short-term care, and (3) outpatient care for general population prisoners.
- Hiring a specified number of psychiatrists (25.5 personnel) and other mental health professionals (246.5 personnel).
- Implementation of procedures for housing assignments, disciplinary proceedings, suicide prevention, access to mental health care, restraint procedures, medication delivery systems, proper placement of mentally ill prisoners, improved medical records, screening procedures, staff training, and delineation of rules for transfer of mentally ill prisoners between prisons.

The Dunn Decree formalized the *Estelle v. Gamble* case and the applicability of deliberate indifference to mental health and mentally ill inmates. In addition, it opened the door for future cases that dealt with proper community linkage of released prisoners with mental health issues. This community linkage philosophy was transformed into what is now known as *prisoner reentry*. According to the U.S. Department of Justice, Bureau of Justice Statistics (2003), *reentry* is defined as a broad term used to refer to issues related to the transition of offenders from prison to community supervision. Reentry seeks to equip offenders returning to society with the resources necessary to become productive members of society. This concept was embraced by the Ohio Department of Rehabilitation and Correction under Director Reginald Wilson and signaled a philosophical switch in prisoner treatment and programming for both mentally ill and other inmates. Thus, the Dunn Decree proved to be important in the overall philosophy of corrections in Ohio and throughout the nation.

As was recognized in the Dunn Decree, community linkage plays a vital role in reducing recidivism for all inmates but is particularly important for mentally ill inmates. The landmark case in the area of community linkage is *Brad H. v. City of New York* (2000). This class action suit, like the Dunn Decree, alleged improper treatment of mentally ill inmates. The major difference in the *Brad H.* case is that it specifically targeted the failure of New York City and St. Barnabas Hospital to provide discharge planning services to jail inmates receiving psychiatric treatment in city jails.

The case complaint in *Brad H. v. City of New York* stated that more than 25,000 inmates per year received psychiatric care while in jail, yet few received discharge planning upon release (Barr, 2003). The case revolved around the practice of releasing inmates (whether or not they were mentally ill) by taking them to a subway station and giving them \$1.50 and two subway fares while providing no other assistance. The *Brad H.* case resulted in a comprehensive reform of the New York City jail mental health system’s practices. It effectively provided inmates with discharge planning for continued mental health treatment after release from jail. It also provided assistance with obtaining related services and benefit entitlements. The discharge planning included the following elements: (a) mental health treatment

and supportive services (including medication and counseling), (b) public benefits (Medicaid, food stamps, etc.), and (c) transportation to housing or shelter.

Medication was mandated to be provided to mentally ill inmates who were released. The settlement required that inmates in need of psychotropic medication must be given a 7-day supply and a 21-day prescription, as well as an escort or transport to a community clinic or mental health treatment center to ensure continuity of care. Another important mandate made staff accountable for obtaining Medicaid benefits for the inmates who were activated or reactivated upon release from jail. This ensured that the inmate would have access to medication and benefits to promote continuity of care after release.

According to Barr (2003), the *Brad H.* case ironically sought mental health discharge planning by means of the following:

Attributing to a jail the obligations long-accepted as duties of community mental health treatment providers and hospitals. In finding that New York City had an obligation to provide discharge planning to Brad H. class members, the Court found that the jails were “subject to licensure” by the State Office of Mental Health and, thus, subject to the same legal requirements as other mental health service providers in New York. (p. 68)

This decision meant that jails and prisons would be looked on as mental health service providers instead of correctional facilities that provide mental health treatment. Thus, it opened the door for the argument that the rights guaranteed to hospital patients extend into prison and jail walls.

The aforementioned court cases outlined the rights of mentally ill inmates in prisons and jails. The impact of these decisions was a significant change in the management of mentally ill inmates.

Prisons and Jails and the Mentally Ill

The final actor in the criminal justice system with which a mentally ill offender comes into contact is the corrections system. In the United States, the corrections system is composed, at its core, of jails, prisons, probation, and parole. In addition, there are numerous ancillary components, such as community-based correctional facilities, halfway houses, electronic monitoring, home incarceration, and global positioning satellite tracking supervision. These are all broken down into two basic categories: (1) incarceration and (2) community supervision. *Incarceration* typically refers to jails and prisons, whereas *community supervision* refers to probation and parole.

Inmates with mental illness make up an increasing number of the U.S. inmate population. In 1999, the jail population of people with mental illness in the United States swelled to 285,000 and approximately 16% of those inmates reported a mental condition or an overnight stay in

a mental hospital (U.S. Department of Justice, 1999). According to a 2006 Bureau of Justice Statistics report, 56% of state prison inmates and 64% of inmates in local jails reported mental health problem. According to that same study, half of mentally ill inmates reported three or more prior sentences. Among the mentally ill, 52% of state prisoners, and 54% of jail inmates, reported three or more prior sentences to probation or incarceration.

The National Institute of Corrections estimates the number of people booked into America’s jails at 10 million per year. Using the aforementioned 16% statistic from the U.S. Department of Justice, one can estimate that nearly 1.6 million people per year with a mental condition or mental illness will pass through America’s jails. According to the Bureau of Justice Statistics (2006), more than half of all prison and jail inmates had a mental health problem. This included more than 784,000 inmates in state and federal prisons and more than 479,000 inmates in local jails.

Characteristics of inmates with mental health problems are indicative of the systemic nature of the problems that arose with the deinstitutionalization of the mentally ill. According to the Bureau of Justice Assistance (2006), inmates 24 years of age and younger reported the highest incidence of mental health problems, and those age 55 and older reported the fewest (Bureau of Justice Statistics, 2006). Many of the inmates reported symptoms of a mental health disorder without a recent history of problems or treatment. This exemplifies the problem of the community-based approach to treating persons with mental illness identified by the Council of State Governments (2008) as letting “individuals with mental illness [slip] through the cracks.” More often than not, those who slip through the cracks end up involved with the criminal justice system.

Inmates with a mental health problem had a violent offense as their most serious conviction 49% of the time, compared with 46.5% of the time for other inmates. Although violent offenses were more prevalent among inmates with a mental health problem, the use of a weapon during the commission of the offense was relatively the same as other inmates: 37.2% and 36.9%, respectively. Reinforcing the notion that mentally ill inmates recidivate more often than other inmates is that fact that 61% of inmates with a mental health problem had a current or past violent offense, compared with 56% of other inmates (Bureau of Justice Statistics, 2006). In addition, according to Los Angeles County officials in 1991, 90% of the Los Angeles County jail inmates with mental illness are repeat offenders. Of these inmates, an estimated 31% have been incarcerated 10 or more times (see <http://www.consensusproject.org>).

Another issue in dealing with mentally ill inmates is their adaptation to the correctional facility. Nearly 58% of inmates who reported a mental health problem were charged with a disciplinary rule violation, compared with 43% of other inmates. Almost 25% of inmates who reported a mental health problem were charged with a rule violation involving assault, and over 20% were injured in a fight. Only 13% of other inmates were involved in an

assault, and 10% were injured in a fight (Bureau of Justice Statistics, 2006). Thus, mentally ill inmates are almost twice as likely as other inmates to be injured in a fight.

The costs of housing mentally ill inmates can quickly add up. According to the Pennsylvania Department of Corrections, housing a mentally ill inmate costs \$140 per day, well above the \$80 per day of other inmates (Wilkinson, 2003). This equates to a 75% increase in cost per day to house a mentally ill inmate. In addition, a Rikers Island study conducted in 2003 indicated that mentally ill inmates are incarcerated three to four times longer than other inmates (Insel, 2003). Some studies have reported that mentally ill inmates are incarcerated up to eight times longer and at a cost of more than seven times that of other inmates (Stephey, 2007). According to Butterfield (1998), the average length of stay in the New York City jail system is 215 days for inmates with a mental illness, compared with 42 days for other inmates. Thus, in addition to increased cost per day and increased time in prisons and jails, mentally ill inmates present operational problems for correctional facilities.

The day-to-day management of mentally ill inmates presents numerous problems for prisons and jails alike. One of the key issues surrounding prison and jail management of mentally ill inmates is that staff does not understand the dynamics involved. Most corrections staff are not appropriately trained to recognize the challenges associated with mentally ill inmates, such as maintaining medication compliance, behavioral issues, noncompliance with institutional rules, and so on. This is evidenced by the Dunn Decree in Ohio and numerous other court actions that have been previously mentioned.

In addition to prison issues, jails present a different challenge for the staff. The jail is often isolated from community mental health programs, or jail staff lack the knowledge of where to find services. The eight most important issues in managing mentally ill inmates, as delineated by the *Standards for the Mentally Ill in Jails* (Blough, 2004), are as follows: (1) reception, (2) housing, (3) programming and services, (4) medical services, (5) discipline, (6) physical plant (i.e., the jail facility itself), (7) linkage (i.e., continuity of care), and (8) staff training.

In attempting to alleviate some of the issues surrounding the management of mentally ill jail inmates, the Ohio Supreme Court Advisory Committee on the Mentally Ill in the Courts formed a subcommittee to address jail standards for the mentally ill. The Ohio Supreme Court Advisory Committee on the Mentally Ill in the Courts is composed of representatives from the Ohio Department of Mental Health, the Ohio Department of Alcohol and Drug Addiction Services, the Ohio Department of Rehabilitation and Correction, the Ohio Department of Mental Retardation and Developmental Disabilities, the Ohio Office of Criminal Justice Services, judges, law enforcement personnel, mediation experts, housing and treatment providers, consumer advocacy groups, and other officials from across the state. This committee, formed by Ohio

Supreme Court Justice Evelyn Stratton, is working to establish local task forces in each county in Ohio to bring similar local representatives together to collaborate on the issues of mentally ill inmates in the criminal justice system. The Jail Standards Subcommittee developed the set of aforementioned model jail standards as a reference point for jail administrators across the nation.

The model jail standards are a professional guide of recommended practices for jail administrators to promote better care of mentally ill inmates while they are incarcerated and, perhaps most important, provide continuity of care throughout the transition from jail to community by implementing appropriate information sharing and safety net systems to ensure that inmates have the requisite services and community linkages to prevent recidivism.

The most important component of the *Standards for the Mentally Ill in Jails* is the first one: reception, when the initial screening of the inmate takes place. From this initial screening, inmates are classified and placed in housing of an appropriate security level. Inmates also are screened for medical and mental illness issues and placed in the appropriate programs or care on the basis of the jail's medical services plan. Many studies have shown that inmates commit suicide within 72 hours of admission to a jail; thus, a comprehensive reception process is vital to the protection of mentally ill inmates.

Another difficult aspect of managing mentally ill inmates falls within the fifth function, discipline. Many mentally ill inmates spend time in disciplinary isolation or lockdown for infractions that, if the proper management team (including a mental health representative) were involved, would not have occurred or may have been viewed as a medical issue instead of a disciplinary issue. In addition, many jails lack the ability to institute therapeutic seclusion when directed by a qualified mental health or medical authority. Thus, the subcommittee has developed standards regarding the construction of a therapeutic seclusion cell that meets minimum guidelines for physical construction while allowing the mentally ill inmate to orient himself or herself to the time of day by providing natural light.

As stated previously, jail staff often lack training in supervising inmates with mental illness. Thus, training standards have been developed for jail staff, including the jail administrator, supervisors, and nonsecurity staff, in regard to recognition, de-escalation, privacy issues, medication responses, and medical contradictions to restraints. In the final analysis, these standards will enable the jail staff to more effectively recognize and properly supervise inmates with mental illness.

Along with drafting standards for mentally ill inmates, the Ohio Supreme Court Advisory Committee on the Mentally Ill in the Courts also advocates community-based treatment and jail diversion programs. These diversion programs are important for both altruistic and financial reasons. Several studies have shown that diverting mentally ill offenders from jails and prisons saves considerable money.

To highlight this cost savings, two programs that provide intensive community-based services to mentally ill individuals who have been involved with the criminal justice system have demonstrated their cost-effectiveness. The Thresholds Jail Program in Cook County, Illinois, demonstrated a cost savings of \$18,873 per program participant. This savings was realized over a 2-year period with 30 participants (<http://www.thresholds.org>). Another project, in Monroe County, New York, Project Link, demonstrated a cost savings of \$39,518 per person over a 1-year period with 44 participants (<http://www.consensusproject.org>).

Federal Legislation

In addition to innovative programs for mentally ill offenders, the federal government has implemented groundbreaking legislation over the past several years. The first piece of legislation, the Mentally Ill Offender Crime Reduction Act of 2003, was designed to promote public safety and community health by facilitating collaboration among the criminal justice, juvenile justice, mental health treatment, and substance abuse systems in diverting mentally ill individuals from the criminal and juvenile justice systems and in treating such individuals within those systems. This act provided \$50 million in grant funding to promote the expansion of mental health courts and to establish community partnerships to better serve mentally ill offenders.

Another piece of federal legislation that had a significant impact on mentally ill offenders was the Second Chance Act. This act was designed to improve outcomes for people returning to the community from prisons and jails. On April 9, 2008, President George W. Bush signed the Second Chance Act into law (see http://reentrypolicy.org/government_affairs/second_chance_act). This legislation authorizes federal grants to government agencies and community and faith-based organizations to provide employment assistance, substance abuse treatment, housing, family programming, mentoring, victim support, and other services that can help reduce reoffending and violations of probation and parole. The House of Representatives appropriated \$45 million to fund these grants.

As a result of these two important pieces of legislation, many new programs have been created or augmented, resulting in better and more cost-effective service to mentally ill offenders. These programs enable communities to tailor their programs to fit both their needs and resources in a community-specific way.

Crime Victimization and the Mentally Ill

Another aspect of mentally ill persons in the criminal justice system that receives little attention is the victim. According to Teplin (1999), persons with serious mental

illness are more than seven times more likely to be a crime victim than those without a mental illness. This population is also 9 times more likely to be the victim of a violent crime and more than 24 times more likely to be the victim of rape. Women with serious mental illness are much more likely to become victims of sexual assault than men.

According to experts, symptoms often associated with severe mental illness, such as disorganized thought processes, impulsivity, lack of awareness of one's environment, and poor planning and problem-solving skills, may compromise one's ability to perceive risks and protect oneself, making one more vulnerable for victimization. In addition, the deinstitutionalization of individuals with mental illness has led to increased vulnerability due to their tendency toward homelessness, substance abuse, and poverty. According to Levin (2005), nearly 3 million severely mentally ill individuals are crime victims each year. The severely mentally ill are more than 140 times more likely than the general population to be the victim of a property crime. In addition to a higher likelihood of being victims, severely mentally ill individuals are more likely to suffer repeat victimization. This is due to symptoms related to their mental illness, which often lead them to be discredited as witnesses or to be found as complicit in their own victimization.

Conclusion

The subject of mental illness and crime is significant in many ways. Mental illness is pervasive in all aspects of the criminal justice system, from offenders to victims. It impacts each segment of the criminal justice system in many ways, from monetary issues to personnel training and interagency collaboration. It is a problem that requires a multifaceted approach to finding solutions. These solutions are generally community specific and agency resource dependent, requiring innovative initiatives and leaders.

NEIGHBORHOOD INFLUENCES ON CRIME

CHRIS L. GIBSON

University of Florida

HOLLY VENTURA MILLER

University of Texas at San Antonio

The typical point of departure for understanding crime is to investigate differences between individuals to discern what characteristics distinguish offenders from nonoffenders, high-rate from low-rate offenders, and persistent from less persistent offenders. It is often the case that psychological, family, biological, social, and environmental factors are front-runners for explaining why people commit crimes. Reinforcing this type of thinking are the media and other news outlets, which often discuss how biological insults and family problems, among others, lead to a particular criminal's behavioral patterns or explain why he or she committed a particular crime. Although much has been learned about why individuals offend, much has also been learned about the striking patterns of crime across geographical entities. As such, focusing only on the individual may not generate an extensive portrait of what explains crime. A neighborhood or community is one geographical example of *place* that can be considered an explanatory source of crime and is the focus of this chapter.

Dating back to the era of Burgess, Park, Shaw, and McKay of the Chicago School of sociology, communities and neighborhoods in the United States have been systematically studied for decades to understand how characteristics of areas within a city are correlated not only with crime but also with other social ills that tend to occur in the same areas. Since the early studies of the Chicago School, criminologists and sociologists have learned a tremendous

amount about crime rates across neighborhoods, correlates of neighborhood crime, and even the offending behaviors of youth living in particular neighborhoods.

According to Sampson (2006, pp. 34–35), a consistent set of “neighborhood facts” have emerged over many decades of research on neighborhood conditions and crime. First, neighborhoods show much variation in terms of inequality. Research has shown that neighborhoods vary substantially in terms of their racial segregation and socioeconomic standing. In fact, neighborhoods that have the highest percentages of minorities are also often the poorest and most isolated neighborhoods. Second, it appears that many problems tend to co-occur in particular neighborhoods. Neighborhoods that have high levels of crime often face other problems, including juvenile delinquency, disorder, higher percentages of infant mortality and low birthweight, school dropout, and child abuse—the list goes on and on. Third, many studies have concluded that neighborhood inequality, segregation, and more generally concentrated disadvantage are often characteristic of neighborhoods with high rates of victimization and the problems mentioned earlier. Fourth, studies that have produced these correlations show consistent findings across various geographical areas investigated. For instance, a correlation between concentrated disadvantage (e.g., poverty and ethnic–racial segregation) and crime is found whether the unit of analysis is the community area, census tracts, police beats, or other classifications of “neighborhood.”

Many of these research facts are the impetus for this chapter, and they will be used to further explore some of the mechanisms responsible for the link between neighborhoods and crime.

This chapter explores several of the “neighborhood facts” just mentioned by discussing theories that attempt to explain why crime rates vary by neighborhoods or communities, research evidence on the specific correlates of crime across neighborhoods, and limitations of research and obstacles facing researchers who are attempting to explain the link between neighborhoods and crime. This chapter also discusses the evidence on how neighborhood contexts influence offending behaviors of adolescents, which are different from crime rates.

Explanations for the Neighborhood–Crime Link: Theory and Research

The notion that neighborhoods may have an influence, or at least something to do with, crime is not an innovative or even a new idea. It dates back to the early 19th century, when two Belgians, Guerry and Quetelet, found patterns of arrest in France to be distributed nonrandomly (Bierne, 1993). Guerry and Quetelet were also some of the first pioneers to discover an empirical link between regional crime rates and structural factors such as poverty rates and education levels. They observed that these relationships were persistent over periods of time. Although Guerry and Quetelet made one of the first empirical links between regional crime rates and social conditions, they did not offer a detailed theoretical explanation for their findings. This led to following two questions: (1) Why are crime rates higher in some places than others? and (2) what are the mechanisms that explain such patterns?

Social Disorganization Theory

One of the classic theories that attempt to make sense of the nonrandom, systematic pattern of crime in regions and cities originates not in Belgium but rather in Chicago and was generated by Shaw and McKay (1942) during the early 20th century when Chicago was experiencing tremendous growth. During its incorporation between the mid-1800s to the early 1900s, the city’s population grew from a few thousand to more than 2 million. This growth was attributable to both the creation of large industries and the arrival of immigrants from European countries (Palen, 1981). With this growth came disorder and crime.

Relying on several existing ideas from social ecology, Shaw and McKay’s (1942) classic formulation of *social disorganization theory* was created to explain crime in places, specifically Chicago neighborhoods. As opposed to being a theory of individual involvement in crime and delinquency, their theory attempts to explain what makes a neighborhood crime prone. Through mapping juvenile

delinquency data on the residential locations of youth referred to juvenile court, Shaw and McKay made several observations regarding neighborhoods and the distribution of crime in Chicago. First, they found a systematic trend in the distribution of delinquency in Chicago; that is, delinquency rates were the highest in lower-class neighborhoods, which were adjacent to areas with industry that had many damned buildings. These lower-class neighborhoods consisted of large percentages of families receiving public assistance and low percentages of families owning homes. These same areas had some of the highest rates of physical decay, infant mortality, prostitution, drug addiction, alcoholism, and tuberculosis. Second, over many decades, Shaw and McKay observed that these neighborhoods continued to sustain high amounts of delinquency and high crime rates, while their racial and ethnic compositions changed substantially. Although a correlation existed between delinquency rates of neighborhoods and concentrations of foreign-born and African American heads of households, Shaw and McKay did not conclude that African Americans or immigrants were any more likely than whites to engage in crime. In fact, they came to the following conclusion:

In the face of these facts it is difficult to sustain the contention that, by themselves, the factors of race, nativity, and nationality are vitally related to the problem of juvenile delinquency. It seems necessary to conclude, rather, that the significantly higher rates of delinquency found among the children of Negroes, the foreign born and more recent immigrants are closely related to existing differences in their respective pattern of geographical distribution within the city. (p. 145)

This suggests that the neighborhood conditions triumphed over individual differences as factors that explain why people commit crime.

In their formulation of social disorganization theory, Shaw and McKay (1942) relied heavily on Park and Burgess’s (1925) *theory of human ecology* to understand why delinquency and crime patterns surfaced as they did in Chicago. Park and Burgess described Chicago as consisting of various concentric zones (Zones 1–5), whereby each zone gradually invaded and dominated its nearest zones, with an overall growth outward. Zone 1 is the central business district and the innermost layer of the city. Zone 2, also referred to as the *zone in transition*, is considered the oldest segment of the city that has experienced the most invasion, dominance, and succession. This zone was observed to be not only the poorest area of Chicago but also the least desirable area to live. Shaw and McKay found some of the highest rates of delinquency and crime, as well as several other social ills mentioned earlier, in this particular zone. Zone 3, the working-class zone, consists of humble homes and rentals largely occupied by people who escaped the poverty-stricken conditions of zone 2 (i.e., the zone in transition). Zones 4 and 5 consist of nicer housing and suburbs, respectively.

Shaw and McKay (1942) interpreted their observations to be a consequence of socially disorganized areas that undermine the control of social disorder and crime. They argued that socially disorganized areas are not able to realize the common values of their residents or reach decisions on how to handle community problems, largely because of a lack of communication and shared values. They identified three indirect indicators of social disorganization: (1) residential instability, (2) poverty, and (3) ethnic-racial heterogeneity, which they argued are highly correlated; that is, areas with higher concentrations of one also have higher rates of the others. First, neighborhoods that have high residential instability have high population turnover whereby individuals move in and out rapidly. Such instability leads to little investment in the community by residents in that they do not care about the neighborhood's appearance or betterment. Also, such high turnover fails to provide residents time to get to know one another, resulting in a decreased sense of neighborliness and failure to recognize their neighbors' children. When out of sight of their primary caregivers, children in such neighborhoods are likely to be under minimal control. Second, although we think of diversity as a good thing these days, ethnic-racial heterogeneity was not seen in Chicago as something good, at least as far as crime was concerned. Racial and ethnic heterogeneity suggests that a neighborhood is populated with diverse races, languages, and cultures, thus creating barriers that isolate groups from one another, which puts limitations on meaningful interactions that could promote shared community values and goals. In socially disorganized neighborhoods, different racial and ethnic groups were known for isolating themselves and having minimal interactions with one another and, as such, lines of communication decreased and disorganization was thought to have increased. Finally, poverty-stricken neighborhoods have insufficient resources, which makes it almost impossible for them to deal with community problems.

A major limitation of Shaw and McKay's (1942) research is that it fell short of permitting them to draw conclusions about how social disorganization related to crime, because they were able to measure social disorganization only by using proxies. Their measures of this concept were limited to the indirect structural aspects of neighborhoods (e.g., poverty and residential instability). Only in theory were they able to state that social disorganization was the force behind the relationships between structural aspects of neighborhoods and crime. Acknowledging this shortcoming, Sampson and Groves (1989) stated that "while past researchers have examined Shaw and McKay's predictions concerning community change and extra-local influences on delinquency, no one has directly tested their theory of social disorganization" (p. 175).

Starting roughly in the 1970s, social disorganization experienced a revival, both theoretically and empirically, from criminologists and sociologists alike who desired to further explain the pieces of the puzzle that were left

undone by Shaw and McKay's (1942) work (see Bursik, 1988; Bursik & Grasmick, 1993; Duncan & Raudenbush, 2001; Jencks & Mayer, 1990; Kornhauser, 1978; Sampson & Groves, 1989; Sampson, Raudenbush, & Earls, 1997; Sampson, Morenoff, & Raudenbush, 2005). Researchers have since filled many gaps by actually measuring and assessing the impact of social disorganization. They have done this by using more advanced research methods and collecting more appropriate data to thoroughly test the propositions from social disorganization theory that were not originally tested.

Sampson and Groves (1989) were among the first to acknowledge that Shaw and McKay (1942) did not sufficiently articulate the differences among social disorganization, its causes, and its consequences. Sampson and Groves defined *social disorganization* as the inability of a neighborhood to achieve common goals of its residents and maintain effective social controls. They developed and tested a model of social disorganization that proposed several hypotheses, one of which consisted of indirect effects of neighborhood structural characteristics on crime. They proposed that structural characteristics (e.g., residential instability, poverty, family disruption, and ethnic-racial heterogeneity) lead to neighborhood social disorganization, which in turn predicts crime. They identified three indicators of social disorganization: (1) weak local friendship networks, (2) low organizational participation, and (3) unsupervised teenage groups. This was an improvement from early social disorganization studies, because social disorganization was closer to being measured and its effects on crime were closer to being estimated. Sampson and Groves used self-report crime and victimization data from individuals residing within neighborhoods, overcoming the problems inherent in Shaw and McKay's use of official crime data. Using data from the British Crime Survey on 238 neighborhoods in England and Wales, they found support for social disorganization theory: Crime rates were higher in neighborhoods where friendship ties were weak, organizational participation was low, and teen groups were unsupervised. Furthermore, their social disorganization variables largely mediated the effects of structural characteristics on crime. This study was replicated a decade later, and the results were highly consistent with those found in the original study (Lowencamp, Cullen, & Pratt, 2003).

Collective Efficacy Theory

In what is probably the most advanced statement to date in the social disorganization tradition of explaining the link between neighborhoods and crime, Sampson and colleagues (1997) put forth a model that has come to be known as *collective efficacy theory*. In this formulation, they developed a concept that they termed *collective efficacy* and argued that it can explain not only the link between structural conditions of neighborhoods and crime rates but also the general well-being of a neighborhood.

Collective efficacy, Sampson and colleagues (1997) argued, is more than just social ties, personal ties, or social networks within neighborhoods. Although networks are important, they must be activated before they are meaningful in assisting with neighborhood problems. Thus, according to Sampson (2006), “Social networks foster the conditions under which collective efficacy may flourish, but they are not sufficient for the exercise of control” (p. 39) So then, what is collective efficacy, and how can levels of it be measured across neighborhoods?

Collective efficacy is defined as social cohesion among neighbors combined with their willingness to intervene on behalf of the common good of the neighborhood. Although this does depend on a working trust among neighbors and social interactions, according to Sampson (2006), it is not a requirement that neighbors befriend one another or that they be friends with local police officers. Sampson and colleagues (1997) developed a measure of this concept that taps into social cohesion, informal social control, and trust among neighbors. The social cohesion and trust component of the measure taps into community relationships and was captured by several survey questions that were asked of residents of various Chicago neighborhoods selected for participation in the Project on Human Development in Chicago Neighborhoods (PHDCN), known as one of the most ambitious and costly criminological studies on neighborhoods in the history of social science. For example, residents were asked if they agreed to the following statements: “People around here can be trusted”; “This is a close-knit neighborhood”; “People around here are willing to help their neighbors”; and “People in this neighborhood share the same values.” The other component of collective efficacy, which captures shared expectations regarding neighborhood social control, was measured using five survey questions asked of residents that included how likely it was that their neighbor could be counted on if children were skipping school and hanging out on a street corner, children were spray-painting graffiti on the side of a building, children were showing disrespect to an adult, a fight broke out in front of their house, and the fire station closest to their home was threatened with budget cuts. These measures of social cohesion/trust and informal social control were so highly correlated that they were summed to form one measure of collective efficacy and then aggregated up to the neighborhood level to reflect the level of collective efficacy for each Chicago neighborhood.

In their theory of collective efficacy, Sampson and colleagues (1997) suggested that the structural conditions of neighborhoods (e.g., poverty, residential instability) do not directly explain crime and that the mediating mechanism is collective efficacy. They argued that a central objective of a neighborhood is the neighborhood residents’ desire to live in safe, crime-free environments where informal social control is practiced to maintain order. For this to occur, groups of neighborhood residents must regulate their

members by developing clear rules and collective goals for the neighborhood. Residents must develop relationships and trust among one another. Sampson et al. argued that when a neighborhood’s residents have a high degree of trust among one another, social cohesion, and practice informal social controls, then both social disorder and crime will be less likely to occur.

Sampson et al. (1997) tested their theory of collective efficacy by analyzing data on 343 Chicago neighborhoods and thousands of residents. These data were collected as part of the PHDCN. They were able to estimate the effects of neighborhood-level structural characteristics (concentrated disadvantage, residential stability, and immigrant concentration) and social processes (i.e., collective efficacy) simultaneously on multiple measures of violence while considering individual characteristics of neighborhood residents (e.g., race, age, mobility, socioeconomic status). To date, this has been one of the most methodologically sophisticated studies on neighborhoods and crime. This research offers several important observations. First, structural characteristics explained a large amount of variability in collective efficacy across Chicago neighborhoods. Second, collective efficacy was found to have an important effect on violence, regardless of structural characteristics and controls for individual characteristics of residents within neighborhoods. Third, neighborhood collective efficacy largely reduced the influence of neighborhood disadvantage on violence, something that is also referred to as a *mediating effect*.

Collective efficacy’s influence in neighborhoods reaches further than just understanding violence. More recently, neighborhood collective efficacy has been shown to partially explain the relationship between disorder and crime in neighborhoods. Ever since the dissemination of *broken windows theory*—that minor crime, if left unattended, will breed larger, more serious crimes—scholars have argued that disorder within a neighborhood leads to crime. Police have thus directed much of their attention to fighting disorder in the hopes of preventing more serious forms of crime from developing. Sampson and colleagues (2002) recently argued that the relationship between disorder and crime is not causal; instead, they both have the same underlying causes, one of which is collective efficacy. Analyzing data from the PHDCN again, they found that the relationship between disorder, measured through direct observations on street blocks, and crime could be explained by the levels of poverty and collective efficacy in neighborhoods.

How Neighborhoods Influence Delinquent and Criminal Behavior of Youth

We now know that social scientists have been intrigued by the association between neighborhood characteristics and crime rates, and how people are affected by the neighborhoods in which they live, for nearly a century. In summary,

research has shown that disorganized and disadvantaged neighborhoods tend to have residents that are less bonded to one another, have limited social networks, lack resources, and tend not to engender mutual trust among one another. In such neighborhoods, residents are less willing to act as informal social control agents to rise up and deal with neighborhood problems (Sampson et al., 1997; Sampson, Morenoff, & Earls, 1999) and are thus unlikely to take action when problems such as crime or juvenile delinquency occur. Beyond crime rates, one area within the social disorganization model receiving attention at present is how neighborhood-level factors influence outcomes for children and adolescents (see Sampson, Morenoff, & Gannon-Rowley, 2002).

Recent research has focused on how neighborhood structure can affect child development, specifically, how it leads adolescents to be more frequently involved with crime and delinquency. Children raised in areas of extremely low levels of socioeconomic disadvantage and inequality are at risk for developing a host of negative outcomes that can further increase their likelihood of participating in criminal activity. Children raised under such conditions are at risk for dropping out of school, lower school achievement, decreased verbal ability, and many other problems (see Leventhal & Brooks-Gunn, 2000). Although researchers have found a link between structural disadvantage of neighborhoods and negative child and adolescent outcomes, until recently the mechanisms for why these relationships exist had yet to be thoroughly explored. Various models have been put forth that may shed light on how neighborhood context can influence children's involvement in crime and delinquency.

Jencks and Mayer (1990) identified five theoretical frameworks for linking individual behavioral outcomes for children and adolescents to the neighborhoods in which they are raised. First, they identified what they called the *neighborhood institutional resource models*, whereby neighborhood resources are believed to affect children and adolescents through access to resources such as parks and libraries, as well as community service centers that promote positive, healthy development. Second, they discussed the *contagion model*, which focuses on problem behaviors and is based on the idea that negative behaviors of peers and/or neighbors can quickly spread throughout a neighborhood, thus affecting children and adolescents. Third, they described a *competition model*, which suggests that neighbors compete with one another for scarce community resources, which in turn can lead to negative behaviors of children and adolescents. Fourth, they noted a *relative deprivation model*, which hypothesizes that neighborhood conditions and surroundings affect children and adolescents by means of their evaluation of their situation vis-à-vis others in the neighborhood. Fifth and finally, they described a *collective socialization model*, which suggests that neighborhoods influence children and adolescents through community social organization; control; and collective efficacy, including the presence of adult role models

and social control agents who, in addition to structuring routines and opportunities in the neighborhood, supervise and monitor children and adolescents in the neighborhood.

Leventhal and Brooks-Gunn (2000) proposed three of their own potential mechanisms by which neighborhoods can influence children. These mechanisms often overlap those described by Jencks and Mayer (1990). The first mechanism is *institutional resources*, the availability of affordable and accessible recreational activities, medical facilities, employment, schooling, and child care for residents of the community. The second mechanism is *relationships*, whereby parental characteristics, such as their mental and physical health, parenting skills, and home life, affect a child. The third mechanism is *norms/collective efficacy*, which focuses on the supervision and monitoring of the behavior of residents within the community (mostly of youth for activities and deviant or antisocial peer group behaviors and physical risk, e.g., violence and victimization). Stressful neighborhood environments cause parents to employ parenting behaviors that adversely affect children's behavior and learning. Prosperous neighborhoods may have more institutional resources that are conducive to child and adolescent well-being, such as learning, social, and recreational activities and quality child care and schools.

Extending beyond the somewhat overlapping neighborhood mechanisms offered by Jencks and Mayer (1990) and Leventhal and Brooks-Gunn (2000), Akers (1998) offered the *social structure social learning (SSSL) model* to explain the link between neighborhood social disorganization and children's delinquent and criminal involvement. According to Akers, children and adolescents learn conforming behaviors through association with others, observation of others, and exposure to others. Similarly, this is also how children and adolescents learn to engage in criminal and delinquent behaviors. Whereas learning theory has been tested and supported through many empirical studies, far less evidence has been put forth regarding Akers's newest formulation of how neighborhood structure and delinquency are linked through the social learning process. In putting forth the SSSL model of crime, Akers (1998) made the following proposition:

Social learning is the primary process linking social structure to individual behavior. Its main proposition is that variations in the social structure, culture, and locations of individuals and groups in the social system explain variables in crime rates, principally through their influence on differences among individuals on the social learning variables—mainly, differential association, differential reinforcement, imitation, and definitions favorable and unfavorable and other discriminative stimuli for crime. (p. 322)

Akers (1998) argued that social learning should largely mediate the link between structural and social conditions of neighborhoods and youth involvement in delinquency and violence. According to Akers, neighborhood social disorganization leads to children and adolescents engaging in

delinquency by means of increased associations with delinquent peers, more positive reinforcement for engaging in delinquent behaviors, exposure to more favorable attitudes toward delinquent behavior, and more delinquent models to imitate. To this end, very few studies have empirically assessed propositions from Akers's SSSL model, and with few exceptions (Haynie, Silver, & Teasdale, 2006) they have largely neglected how peer associations of children and adolescents can mediate the effect neighborhood conditions may have on delinquent behavior. Although Akers's model should not be viewed as competing against these other models, it should be seen as an additional piece of the theoretical puzzle that can help us understand why children residing in disadvantaged neighborhoods are at risk for engaging in more delinquency and crime.

Conclusion

The goal of this chapter was to provide an introductory overview of the link between neighborhoods and crime. First, several neighborhood facts were discussed that have been confirmed by years of research on neighborhoods and their social conditions. Second, some of these facts, such as the link between neighborhood structural conditions and crime, were discussed from theoretical perspectives. Specifically, social disorganization and collective efficacy theory were introduced as key theoretical explanations for the link between neighborhood structural conditions and crime. Research support for both of these theories was discussed, and various theoretical perspectives on how neighborhood contexts in which children grow up can influence their involvement in delinquent and criminal behaviors were discussed. This final section discusses various limitations and some future directions for research on neighborhoods and crime.

As described earlier, many advances have been made in the arena of neighborhood research since the early discoveries of Guerry and Quetelet, the Belgian researchers who discovered correlations between regional crime rates and social factors in France during the 1800s. Starting with Shaw and McKay's (1942) findings and theory to the most recent advances by Sampson and his colleagues (e.g., Sampson & Groves, 1989), we know much more today about neighborhood influences on crime than we did a century ago. Nonetheless, several obstacles stand in the path of understanding the impact and reaching effects of neighborhood conditions on crime and how to prevent crime in neighborhoods.

First, one of the most important obstacles facing neighborhood research is the issue of *selection bias*. To understand the effect of any neighborhood influence on crime, research must be able to account for the types of families and adolescents living in those neighborhoods, because families are not randomly assigned to live in a particular neighborhood. Instead, they often choose which neighborhoods they live in; some have limited choices as to the

neighborhoods in which they can afford to live. This poses the following questions: How do we truly know that neighborhood-level differences in crime rates are the consequences of neighborhood level factors, such as collective efficacy? Could differential crime rates be attributed to the types of families and children who live in those neighborhoods and not the neighborhood conditions themselves? Some recent research carried out in large cities such as Boston and New York has attempted to address this issue by moving families and their children from high-poverty neighborhoods to lower poverty neighborhoods. This is known as the Moving to Opportunity study (Goering & Feins, 2003). It has been able to address the issue of selection bias because families were randomly assigned to live in various neighborhoods. In general, the study has found that families who moved to lower poverty areas had more positive outcomes, especially in the children's problem behaviors; however, these effects are not totally consistent across sites. As Sampson (2006) pointed out, however, the Moving to Opportunity study does not address the causal effects of neighborhood conditions on crime rates. For this to be accomplished, a researcher would need to randomly assign treatments or programs to neighborhoods and then assess how the crime rates change over time while comparing the treated neighborhoods with those that did not receive treatment.

Second, many neighborhood-level factors have been discovered that help us understand crime within and between neighborhoods, but less is known about how to use this research in a way that will reduce neighborhood crime rates. For instance, it appears that collective efficacy is a very important correlate of crime. In fact, Pratt and Cullen (2005) conducted a recent review of 200 studies on macrolevel predictors of crime. They discovered that collective efficacy ranked fourth in the mix of factors that were important for explaining crime rates. Although we now know that collective efficacy is an important neighborhood-level influence, what we do not know is how a neighborhood without collective efficacy can achieve it. Few, if any studies, have explicitly focused on increasing collective efficacy at the neighborhood level.

Third, although we now know considerably more about how crime rates are influenced by structural and social conditions of neighborhoods, less is known about how neighborhood contexts influence the development of children and adolescents in terms of their delinquent behavior. This is largely because scholars do not have the required data and methodological sophistication to analyze many children and their families from various neighborhoods in a city. Such a study would require an amazing amount of resources and money. However, now studies are under way, and some (e.g., the Project on Human Development in Chicago Neighborhoods) have even been completed. These types of studies (i.e., that assess how neighborhood conditions influence the behavior of children and adolescents) are becoming important developments in the research literature.

As for neighborhood contextual influences on delinquent and offending behaviors of youth, several scholars (Leventhal & Brooks-Gunn, 2000; Wikström & Sampson, 2003) have outlined key areas for further improvement and expansion of the understanding of mechanisms by which neighborhood conditions may lead to adverse outcomes for children. They argue that the reasons why neighborhood characteristics impact developmental and behavioral outcomes are important areas of inquiry currently lacking a substantial empirical base. Their recommendations are very similar. First, they propose that community organization and socialization are likely more important than structural aspects of neighborhoods (e.g., concentrated disadvantage, residential instability). An important candidate in this arena is *child-based collective efficacy* (Sampson et al., 1999), which consists of the willingness of residents to share responsibility for children and is largely contingent on conditions of mutual trust and shared expectations between residents. These characteristics include intergenerational closure, reciprocal exchange, and child-centered social control, which together represent neighborhood aspects of child rearing or collective efficacy for children (see Sampson et al., 1999).

According to Sampson et al. (1999), *intergenerational closure* indicates the closeness of parents and children within a community, and it is argued that this closeness is important for neighborhood control of children beyond parental child-rearing practices and monitoring in that it provides social support for children and information to parents and helps in facilitating control. For instance, examples of such questions include whether there are adults whom children can look up to in the neighborhood and adults in the neighborhood who can be counted on to watch that children are safe and do not get into trouble. *Reciprocal exchange* is the interaction of families with respect to child rearing (both parent and children); such exchanges can involve giving advice, material goods, and information about child rearing. For example, questions may include: How often do people in the neighborhood do favors for each other? How often do people in the neighborhood visit in each other's homes or on the street? *Child-centered social control* relates to the collective willingness of residents to intervene on behalf of children in the neighborhood, and it represents a neighborhood's willingness to take action to help monitor and look after children. In studies of child-centered social control, residents are asked whether their neighbors would do something if youth were skipping school and hanging out, spray-painting graffiti, or showing disrespect to an adult.

In their review of neighborhood influences and youth development, Wikström and Sampson (2003) argued that the development of criminal propensities is partially influenced by community socialization and that this impact is due to the level of collective efficacy present in the neighborhood. Collective efficacy is likely related to the frequency in which children experience behavioral settings that are not conducive to prosocial development. Specifically,

children living in neighborhoods that are low in child-based collective efficacy might be expected to frequently encounter behavioral settings that provide less parental support and fewer positive role models. Wikström and Sampson also indicated that neighborhoods can exert a direct effect on child and adolescent development. Finally, both Sampson et al. (1999) and Wikström and Sampson agree that a lack of empirical evidence prevents researchers from drawing any conclusions as to which theoretical models are most important, which, at present, limits the advancement of a contextual model of neighborhood influences on children.

Researchers have yet to determine whether neighborhood structural and social processes interact with children's personal attributes to ameliorate or amplify their involvement in delinquency, the age of onset of delinquency, the frequency in which they engage in delinquency, and whether they persist in delinquency and crime. These are issues that are still being theoretically developed and lack systematic research. Only with time; many resources; the correct methodological designs; appropriate analytic strategies; and quality data on neighborhoods, crime, and youth will these complex issues regarding the link between neighborhoods and crime be adequately addressed.

EMPLOYMENT AND CRIME

ROBERT APEL

State University of New York at Albany

Employment has long been observed to be a correlate of criminal behavior. For example, Belgian criminologist Adolphe Quetelet, in an 1831 publication analyzing French crime statistics titled *Research on the Propensity for Crime at Different Ages* (cited in Beirne, 1987), remarked that individuals who were unemployed or employed in “lowly occupations” were more likely to commit crimes (Beirne, 1987, pp. 1153–1154). Thus, the study of crime and the economy is a long-standing tradition in criminology.

To maintain a sufficiently narrow scope, this chapter focuses on individual-level theories of, and observational research on, the relationship between employment and crime. It thus omits a review of employment–crime studies at the macro level and experimental or quasi-experimental evaluations of employment interventions. The first section in this chapter comprises a theoretical overview of the relationship between employment and crime. The second section reviews the empirical literature on the employment–crime connection, the third section identifies empirical challenges that must be overcome in employment–crime research, and the final section offers some concluding remarks and outlines future directions.

Theoretical Relationship Between Employment and Crime

A number of theories rooted in labor economics and sociological criminology consider legitimate, remunerative

employment to be an important causal factor in the prevention of criminal behavior. Conversely, unemployment is believed to genuinely cause an increase in criminal activity. Several of the more prominent theories of the employment–crime relationship are described in this section.

Economic choice theory is rooted in the neoclassical idea of *utility maximization*, which presumes that people are responsive to incentives and choose behavior by maximizing their utility from a stable set of preferences, subject to opportunities and other constraints on their resources (Becker, 1968). Distilled to its basics, the economic choice theory of crime is concerned with how self-interested individuals allocate their time and resources between legal and illegal activities when the returns to the latter set of activities in particular are uncertain. Prominent in this tradition is the *expected utility model*, according to which a person decides to commit crime when the expected returns from illegal behavior, discounted by punishment risk, exceed the expected returns from law-abiding behavior such as employment. All else equal, individuals faced with current or future unemployment or low wages experience lower costs of committing crime. To be precise, they experience lower *opportunity costs* of engaging in illegal activity, and thus they find illegal income generation to be an attractive and rational alternative compared with legal income generation.

Social control theory proposes that strong attachment to the institution of work constitutes a potent source of informal social control over criminal behavior (Hirschi, 1969; Sampson & Laub, 1993). Such attachment encourages a

strong “stake in conformity” that can overcome the temptation to violate the law, in part because attached individuals fear putting their future careers in jeopardy. The acquisition of a stable job of high quality can also be a turning point for individuals with a history of criminal behavior because it fosters *social capital*, or investments in conventional institutional relationships (Hagan & McCarthy, 1997; Sampson & Laub, 1993). According to control theory, then, the mediating role of social capital implies that work quality is more salient than the mere presence of work, because higher quality jobs promote stronger interpersonal connectedness and institutional embeddedness.

Social control theory is also friendly to the notion that “idle hands are the devil’s workshop,” in the sense that employed individuals simply have fewer opportunities to commit crime because they are too busy working (Hirschi, 1969). This is the involvement hypothesis of the theory: “Many persons undoubtedly owe a life of virtue to a lack of opportunity to do otherwise” (Hirschi, 1969, p. 21). If the allocation of time is a zero-sum game, then one more hour spent in the workplace is one less hour available for criminal activity outside the workplace. In a recent elaboration of this idea, Laub and Sampson (2003) proposed that attachment to work not only constrains opportunities to commit crime but also leads to fundamental changes in how individuals spend their leisure time outside of work. The imposed structure of the workplace may permeate nonwork settings and thus foster changes in routine activities that lure individuals away from crime by channeling them into conventional behavior with law-abiding companions.

Strain theory presumes that lack of success in the legitimate labor market motivates individuals to “innovate” in the most expedient or technically efficient manner, usually through criminal behavior (Merton, 1938). Underlying this theory is the presumption that the desire for wealth is universal (it is a culturally approved goal) and therefore blocked access to legitimate opportunities to acquire this valued goal results in anger, frustration, desperation, or other forms of negative affect (see Agnew, 1992). Criminal behavior is one way to alleviate the negative feelings associated with the strain of unemployment or low-quality employment. Unemployed individuals thus commit crime as an income substitute; individuals employed in low-wage or low-quality occupations commit crime as an income supplement.

According to various strands of *learning theory*, the workplace provides a context for differential associations with conventional employers and coworkers that tip the balance of definitions favorable to law violation (Sutherland, 1947), a general process proposed to operate through modeling and differential reinforcement of law-abiding behavior (Akers, 1985). Steady work in a good job puts individuals in close proximity with a conventional social circle for a nontrivial number of hours each week. As such, they have exposure to colleagues who espouse prosocial beliefs toward the law, who act on these beliefs, and who therefore provide positive role models and reinforcers for behavior both inside and outside the workplace.

To summarize thus far, all of the foregoing theories provide support for two basic propositions. First, individuals who are employed are less likely to commit crime, on average, compared with individuals who are not employed, who are unemployed, or who are underemployed. Second, individuals who are employed in stable, high-quality jobs (e.g., high-paying, primary-sector occupations) are less likely to commit crime than their counterparts in unstable, low-quality jobs. Each of the foregoing theories—economic choice, social control, strain, and learning—presumes that the inverse correlation between gainful employment and crime is causal; however, according to at least one other prominent theoretical tradition, the employment–crime correlation is entirely spurious.

Self-control theory posits that individuals sort themselves into certain institutional settings on the basis of a differential tendency to consider the long-term consequences of their actions, what Gottfredson and Hirschi (1990) referred to as *self-control*. Because individuals with low self-control seek immediate gratification of their desires with minimal effort or long-term planning, they are less likely to be employed or, if they are employed, will have difficulty holding down a steady job: “People who lack self-control tend to dislike settings that require discipline, supervision, or other constraints on their behavior” (Gottfredson & Hirschi, 1990, p. 157). It so happens that these same personal qualities increase the likelihood that desires will be satisfied through criminal activity. Simply put, unemployment, low-wage employment, and crime are all manifestations of the versatility of individuals with low self-control. In statistical terminology, low self-control is a source of unobserved heterogeneity that is responsible for an artifactual (i.e., spurious) inverse correlation between employment and crime.

The Empirical Relationship Between Employment and Crime

More than two dozen empirical studies among a variety of adult and young adult populations consistently confirm that labor market success in the form of employment, high wages, job stability, and occupational prestige are correlated with reduced criminal involvement (Crutchfield & Pitchford, 1997; Farrington, Gallagher, Morley, St. Ledger, & West, 1986; Good, Pirog-Good, & Sickles, 1986; Grogger, 1998; Hagan & McCarthy, 1997; Horney, Osgood, & Marshall, 1995; Laub & Sampson 2003; Sampson & Laub, 1993; Thornberry & Christenson, 1984; Uggen, 1999, 2000). Instead of reviewing each study in detail, a handful are selected that are representative of the wider literature and offer valuable insight into the employment–crime connection.

Thornberry and Christenson (1984) studied the relationship between unemployment and crime among a cohort of males born in 1945 in Philadelphia. In an analysis of yearly crime and unemployment during the 21–24

age range, unemployment duration was positively correlated with officially recorded arrest frequency (weighted by seriousness). They also found that the correlation grew stronger with age and that the correlation was more pronounced among the less advantaged individuals in the sample, including delinquent persons, African Americans, and individuals from blue-collar families.

Farrington et al. (1986) assessed the impact of unemployment on crime among a sample of 16- to 18-year-old working-class London men. They found that rates of officially recorded convictions were higher during periods of unemployment. When they administered a prediction scale of delinquency at age 10 (e.g., low income, poor parental child rearing, low intelligence, parental conviction), they found that unemployment was significantly related to crime only among participants with the most risk factors. This finding suggests that unemployment is criminogenic only among individuals with a high propensity for crime and therefore may not cause crime among generally low-risk individuals. Stated differently, employment may be associated with the largest crime-preventive benefits among high-risk individuals, but it may have little or no impact on crime among low-risk persons.

Sampson and Laub (1993) used data from a sample of young males sentenced to a Boston-area reform school and matched them with a sample of schoolgoing youth. They constructed a measure of job stability that was a composite of employment status at the time of the interview, duration of the most recent employment, and work habits as indicated by reliable and effortful work performance. They found that job instability during the 17–25 age range was correlated with higher probability, frequency, and hazard of arrest during the 17–25 and 25–32 age ranges, net of official and unofficial juvenile delinquency. A follow-up of a subset of the reform school sample to age 70 revealed that arrest frequencies were significantly higher during months in which the participants were unemployed compared with months when they were employed (Laub & Sampson, 2003).

Grogger (1998) assessed the relationship between wages and crime among nonenrolled males (i.e., those not in school) in a national probability sample. He reported that higher wages corresponded with a substantially lower probability of criminal participation, controlling for prior criminal justice involvement. Further inspection of the data led Grogger to conclude that the African American–white wage gap accounted for about one quarter of the racial differential in crime participation. Moreover, he found that the age-earnings profile could plausibly explain the age distribution of crime from the late teens to the early 20s, leading him to conclude that “the growth in market opportunities with age is largely responsible for the concomitant decrease in crime” (p. 786).

Uggen (1999, 2000) has studied the employment–crime relationship among a sample of males who were part of a larger study of supported work for high-risk individuals. In one study, he found that job quality (measured objectively by aggregate job satisfaction scores on the Quality of

Employment Survey) was inversely associated with self-reported crime among a sample of ex-offenders who were successful in finding work (Uggen, 1999). This was true even when he controlled for prior criminality and substance abuse and when he considered both economic and noneconomic crime as outcomes. In a second study, he found that a work opportunity was a significant turning point in the criminal careers of individuals with an arrest history (Uggen, 2000). Securing employment—even marginal employment—through a random assignment process was associated with a lower hazard of illegal earnings and arrest. He also found that older offenders (over age 26) benefited the most from this work experience.

By way of summary, empirical studies confirm the expectation from a variety of theories that having a job is associated with less crime than not having a job and that being unemployed is associated with more crime than being employed or out of the labor force. It also appears to be the case that having a good job—more stability, higher wages, better quality—is associated with even less crime than having a bad job, although even a bad job is still associated with less crime than unemployment, at least among high-risk samples (e.g., Hagan & McCarthy, 1997; Uggen, 2000). However, it should be noted that the strength of the correlation between employment and crime is not as impressive as one might anticipate from theoretical arguments. The correlation is often quite weak once other characteristics are controlled. Two other noteworthy findings are that the employment–crime connection tends to be stronger among older individuals as well among high-risk individuals. On the other hand, employment is not so strongly associated with crime among young persons and generally low-risk individuals (e.g., Farrington et al., 1986; Thornberry & Christenson, 1984; Uggen, 2000).

The Special Case of Adolescent Employment and Delinquency

Almost all U.S. adolescents gain employment experience before they graduate from high school, with as many as 90% of teenagers entering the labor market at some point during their high school careers (National Research Council, 1998). A nontrivial proportion of employed adolescents also work at *high intensity*—a label denoting employment of more than 20 hours per week (Greenberger & Steinberg, 1986). Folk wisdom would suggest that intensive exposure to the world of adult work provides a number of positive benefits for adolescents because of the way that it structures a youth’s leisure time, increases exposure to adult authority figures, fosters independence and maturity, teaches responsibility in the use of money, and promotes balancing of multiple responsibilities. Surprisingly, however, empirical research has consistently demonstrated that “the correlates of school-year employment are generally negative” (Steinberg & Dornbusch, 1991, p. 309). This is especially true where delinquent behavior is concerned.

In the 1980s and 1990s, a generation of studies of youth employment and antisocial behavior emerged that gave more sustained attention to the developmental consequences of adolescent employment (Agnew, 1986; Bachman & Schulenberg, 1993; Mortimer, 2003; Steinberg & Dornbusch, 1991; Wright, Cullen, & Williams, 1997, 2002). The seminal work of this new generation of research was a book by Greenberger and Steinberg (1986), titled *When Teenagers Work: The Psychological and Social Costs of Adolescent Employment*. Their unambiguous conclusion was that “extensive commitment to a job may interfere with the work of growing up” (p. 7). Research by Greenberger and Steinberg and others has consistently found that working during high school was associated with higher rates of school misconduct (e.g., truancy, cheating, suspension), substance use (e.g., cigarettes, alcohol, marijuana), minor delinquency (e.g., theft, vandalism), and serious delinquency (e.g., interpersonal aggression, assault). Moreover, researchers discovered that these negative side effects of employment were generally a function of work intensity, or the number of hours per week devoted to working. Specifically, intensive employment of more than 20 hours per week was associated with the most negative outcomes.

By the late 1990s, the scientific consensus was that work of moderate intensity (1–20 hours per week) has few adverse effects and in some cases is more developmentally beneficial than not working at all. However, beyond this 20-hour threshold employment appeared to be associated with more costs than benefits for the social and emotional development of young people. The finding that intensive employment during adolescence increases the risk of delinquency is puzzling in light of the research on adult employment reviewed earlier, which consistently indicates that adults who are strongly attached to work and who acquire full-time (read: intensive) employment are less likely to be criminally involved. These contradictory results have forced researchers into the awkward position of suggesting that the sign of the work effect changes at some point during the transition to adulthood, that is, that strong attachment to work (as measured by the number of hours per week) is criminogenic for adolescents but prophylactic for adults (e.g., Uggen, 2000, p. 530; Wright et al., 2002, p. 10).

Fortunately, employment–crime theories are sufficiently flexible to accommodate the apparent anomaly of adolescent work. One set of explanations appeals to the *job quality thesis* of traditional economic and sociological theories. Teenage employment is concentrated in the retail and service industries, in occupations that are universally regarded as low quality. These jobs pay barely more than minimum wage, involve little in the use or acquisition of any notable skills, offer few or no benefits or opportunities for upward mobility, and suffer constant turnover. They are often derided as teenage “McJobs” that do not engender any significant degree of attachment on the part of adolescent workers. Moreover, they tend to involve stressful working conditions and are often a stopping point for high school dropouts. Thus, it does not require theoretical

acrobatics to explain why adolescent employment may be criminogenic. Low-quality jobs lead to crime among adolescents and adults alike; it just happens to be the case that the typical job for the typical adolescent is a low-quality one and thus a criminogenic one (see Staff & Uggen, 2003, for evidence on “good jobs” in adolescence).

Another set of explanations focuses attention on adolescence as a life stage and is more firmly rooted in developmental psychology and theories of precocious development. Put simply, intensive employment is one symptom of a latent, stage-specific propensity to expedite the transition to adulthood before adolescents have acquired the maturity to do so. The underlying issue for precocious development theory thus has to do with early timing of work, or developmentally “off-time” entry into the work role and especially an intensive work role. According to this perspective, the family and school are the primary socializing institutions in adolescents’ lives, with the workplace taking on secondary importance until the postsecondary years. With respect to family relationships, intensive employment disrupts healthy parent–child relationships, because these youth spend less time with, are less emotionally close to, engage in more disagreements with, are less closely monitored by, and exercise greater decision-making autonomy vis-à-vis their parents than nonworkers or moderate workers (Bachman & Schulenberg, 1993; Steinberg & Dornbusch, 1991). In schooling domains, intensive employment is associated with disinvestment in and disengagement from school, because it is correlated with less time spent studying and doing homework, cutting class and absenteeism, lower educational aspirations, a nonacademic track curriculum, negative school attitudes, and lower scholastic performance (Agnew, 1986; Steinberg & Dornbusch, 1991). Therefore, embeddedness in a developmentally unproductive work role competes with family and school as the dominant influence in the lives of adolescents and leads to a variety of delinquent and deviant adaptations (Wright et al., 2002).

Irrespective of the explanatory mechanism, until recently there was virtual unanimity that youth employment was criminogenic (with notable exceptions, e.g., Good et al., 1986). However, a new round of youth employment research has emerged in the 2000s that strongly challenges the interpretation of the employment–delinquency association as causal (Apel, Paternoster, Bushway, & Brame, 2006; Apel, Bushway, Paternoster, Brame, & Sweeten, 2008; Apel et al., 2007; Brame, Bushway, Paternoster, & Apel, 2004; Paternoster, Bushway, Brame, & Apel, 2003). This research has been attentive to the fact that adolescent workers (especially high-intensity workers) are different from moderate workers and nonworkers, often well before they begin working. For example, youth tend to enter the labor market in part as a result of weak emotional attachment to their parents, academic underperformance and school disengagement, and early delinquent and antisocial behavior (see Apel et al., 2007; Bachman & Schulenberg, 1993; Mortimer, 2003; Steinberg et al., 1993). In other words,

youth with a higher propensity for crime are precisely those most likely to work intensively while in school. This implies that the apparent criminogenic effect of youth employment may be a selection artifact instead of the true causal effect of employment on delinquent behavior.

Empirical Challenges to Studying the Employment–Crime Relationship

Any study of the causal effect of employment on crime must confront at least two empirical challenges: (1) endogeneity and (2) simultaneity. These are threats to causal inference that can seriously bias empirical estimates of the employment–crime association. Each is discussed in turn, and recent efforts to overcome these challenges are described.

Endogeneity: The Selection Problem

One of the most serious challenges to existing studies of employment and crime is the selection problem. It is the problem of *endogeneity* of employment effects on crime, meaning that individuals who are employed (or are employed in high-quality jobs) differ fundamentally from individuals who are not employed in a way that accounts for their lower crime involvement. One may conceive of such person-level characteristics as ability, planfulness, and agreeableness that might individually or jointly increase the likelihood that an individual will be gainfully employed and simultaneously reduce the likelihood that the person will commit crime. The selection problem arises when these traits are difficult or impractical to observe and measure. The consequence is systematic bias in the estimated effect of employment on crime. Moreover, the direction of the bias under this scenario is predictable: The impact of employment on crime will be overestimated.

Sampson and Laub (1993) found that weak occupational commitment and job instability from ages 17 to 32 were predicted by official delinquency, unofficial delinquency (self-, parent, and teacher report), and early temper tantrums (parent report) during childhood. Caspi, Wright, Moffitt, and Silva (1998) linked youth unemployment (ages 15–21) with a variety of factors that reach far back into childhood. As measured in early childhood (ages 3–5), longer duration of unemployment was predicted by low family occupational status, low intelligence, an unmarried mother at birth, and difficult temperament. As measured in late childhood (ages 7–9), youth unemployment was predicted by these same variables in addition to family conflict and behavior problems. An important contribution of these studies is that they directly address the selection problem and identify underlying factors responsible for the differential sorting of individuals into the labor market, oftentimes long before they do so.

Under these circumstances, causal inference about the nature of the employment–crime relationship is aided by the

availability of longitudinal data, which allow researchers to overcome endogeneity of the employment effect on crime attributable to time-stable individual differences, so-called unobserved heterogeneity (e.g., Horney et al., 1995). Such studies have examined the way in which change in employment affects change in crime and have found that the employment–crime relationship (at least among adults) does withstand these more rigorous selection controls and is not seriously biased by endogeneity. However, it is worth noting that the strength of the correlation tends to be weak compared with other time-varying factors, such as drug consumption and living arrangements (e.g., marital living and cohabitation).

The consequences of the selection problem have been brought into sharp focus in recent youth employment research. Paternoster et al. (2003) and Apel et al. (2006) have addressed the selection problem using longitudinal data on employment and antisocial behavior for 3 years. Both studies replicated the positive correlation between intensive employment during the school year and delinquent behavior using conventional methods. However, both also found that intensive work was positively correlated with delinquency only when examined across individuals but that within-individual change in work involvement was not correlated at all with change in delinquent behavior and substance use. They concluded that the criminogenic effect of intensive work among adolescents was driven by a process of selection rather than causation and could be best understood as a spurious correlation.¹

In one of the most recent statements on the subject of adolescent employment, Apel et al. (2008) exploited interstate variation in child labor laws at the 15-to-16 transition as a source of causal identification. They found in their analysis that work intensity was actually inversely correlated with delinquent behavior; that is, the increase in work involvement from age 15 to 16 attributable to a loosening of child labor restrictions (the magnitude of which varied across states) was actually associated with a substantial decline in delinquent involvement. Once the problem of endogeneity was addressed through the use of longitudinal data and instrumental variables, then, the employment–delinquency association was found to be inverse after all, contrary to most previous youth employment research but well in line with employment–crime research among adults. Moreover, the techniques that Apel et al. used allowed them to interpret this as a causal association.

Simultaneity: The Feedback Problem

The contemporaneous, inverse correlation between employment and crime is usually interpreted as the causal effect of employment on crime. However, the correlation may in fact represent the causal effect of crime on employment, which is the feedback problem. This is the problem of *simultaneity* of causal effects, in that employment and crime mutually influence one another. The practical consequence of simultaneity bias is to systematically overestimate the

effect of employment on crime, because the simultaneous inverse effect of crime on employment will be erroneously attributed to the effect of employment on crime.

Labeling theory, for one, anticipates just this sort of feedback effect from crime to employment. This is the notion of *secondary deviance*, or *deviance amplification*, among persons toward whom a sanction has been directed. An arrest or conviction, for example, constitutes a social stigma that might lead to exclusion from legitimate employment (Pager, 2003). Many prospective employers may be disinclined to hire individuals with a criminal record because it serves as a signal of sorts about what kind of employee one is likely to be. For example, employers may be sensitive to liability for negligent hiring (Bushway, 2004), or they may perceive offenders as untrustworthy (Waldfogel, 1994). A criminal record may also relegate individuals to the secondary labor market, or to what Nagin and Waldfogel (1995) referred to as “spot market jobs” as opposed to “career jobs.” This effect may be attributable, in part, to state-imposed restrictions on employment in certain industries (e.g., government employment), catering to vulnerable clientele (e.g., children), and professional licensing in certain occupations (Burton, Cullen, & Travis, 1987).

Empirical research confirms that a criminal record in the form of arrest, conviction, or incarceration does indeed hamper an individual’s future employment prospects (e.g., Nagin & Waldfogel, 1995; Waldfogel, 1994; Western, 2002). A criminal record reduces employment, increases unemployment, lowers earnings, slows wage growth, diminishes job tenure, and exacerbates job turnover. Thus, the feedback problem is real, and research that examines the contemporaneous effect of employment on crime must be attentive to simultaneity bias that overstates the preventive effect of employment on crime.

One way that researchers have addressed the feedback problem is through estimation of reciprocal models of employment and crime. *Simultaneous equation studies* have confirmed that the cross-sectional association between employment and crime is a combination of the effect of employment on crime as well as the effect of crime on employment (e.g., Good et al., 1986; Thornberry & Christenson, 1984). In these studies, isolation of causal effects requires the use of exclusion restrictions (i.e., instrumental variables) or other modeling constraints that are capable of identifying the simultaneous effects in the model. Thornberry and Christenson (1984) imposed cross-time equality constraints on model parameters to identify the reciprocal effects of unemployment and arrest. Good et al. (1986) used the number of job rejections as an instrumental variable for employment and gang affiliation and police enforcement (specifically, police contact) as instrumental variables for arrest. Each of these studies found that the effect of (un)employment on arrest was stronger than the contemporaneous feedback effect of arrest on (un)employment. In fact, both studies discovered that the contemporaneous effect of arrest on (un)employment was not statistically significant, although Thornberry and Christenson discovered that the

influence of arrest was lagged one period, and Good and colleagues noted that the total number of prior police contacts was more salient. These studies thus suggest that the influence of criminality on employment operates through the accumulation of an arrest record that impedes the acquisition of stable employment.

Conclusion

The question of the relationship between employment and crime has a long history in criminology and dates back to the earliest studies of crime beginning in the mid-19th century. Empirical criminology has repeatedly confirmed the presence of an inverse correlation between employment and crime, and research that has addressed the selection and feedback problems in a compelling way points to the correlation as a causal one. However, as noted earlier, the strength of the employment–crime correlation is not nearly as impressive as a number of theoretical accounts would suggest. Neither has research successfully pinpointed the precise theoretical mechanism for the correlation. Nevertheless, there is sufficient evidence to date that continued exploration of this relationship is justified that would illuminate the causal pathway.

A handful of more recent studies have endeavored to do just that by considering heterogeneity in the employment–crime relationship. These studies are based on the presumption that employment may not have the same crime-control benefits for all members of a population. The *population average treatment effect* of employment on crime will not be meaningful if it is not representative of the *group average treatment effect* for any identifiable subgroup in the target population. It could be, in other words, an average over a possibly wide range of subgroup averages. Relatively more recent studies have found that the strength of the employment–crime correlation varies as a function of the aggregate labor market context (Crutchfield & Pitchford, 1997), specific characteristics of the job (Staff & Uggen, 2003), and individuals’ offending history (Apel et al., 2007; see also Farrington et al., 1986; Thornberry & Christenson, 1984). Studies such as these identify important pathways for further empirical and theoretical exploration.

Note

1. A simulation study conducted by Brame et al. (2004) was incapable of identifying even the *sign* of the causal effect of work on delinquency. In other words, they could not determine with confidence whether the correlation between employment and delinquency was positive, zero, or negative. All three possibilities were consistent with the data, depending on what assumptions they were willing to adopt. Importantly, they concluded that if an unobserved “crime trait” increased the probability of employment and also increased the probability of delinquent behavior (both of which are consistent with prior research), the estimated work effect could actually be shown to be negative.

PEERS AND CRIME

DANA L. HAYNIE

The Ohio State University

Peer relations have long been central to the study of delinquency, and for good reason. Adolescents spend much time with their friends, attribute great importance to them, and are more strongly influenced by them during this period of the life course than at any other time. During adolescence, friends become the primary role models, and adolescents are particularly vulnerable to peer dynamics. Thus, it is not surprising that one of the most consistent and robust findings in the criminology literature is that adolescents with delinquent peers are more likely to be delinquent/criminal themselves. This finding dates back to the 1930s with Shaw and McKay's (1942) discovery that more than 80% of juveniles appearing before court had peer accomplices. More recent studies have found that the relationship of peer delinquency to self-report delinquency is more important than that of any other independent variable, regardless of whether the focus is on status offenses, minor property crimes, violence crimes, or substance use.

Although prior research establishes that adolescents are likely to behave in a manner consistent with their friends, it has only recently begun to incorporate the network structure of friendship relations into empirical models. By ignoring the underlying social structure of friendship patterns, prior research has failed to adequately measure peer delinquency and to incorporate the structure in which peer processes operate. Therefore, one aim of this chapter is to illustrate how a network perspective can provide a particularly useful lens through which to better understand the

importance of peers for adolescent involvement in crime and delinquency. The following sections discuss the importance of friendship networks in adolescence.

Friendship Networks

Ethnographic studies of adolescents in school settings provide important information on the role of friendship networks during adolescence. These studies reveal that being with friends is a very important aspect of school life for most students and that relational problems with peers are particularly distressing to adolescents. Part of the importance attributed to friendships derives from structural changes that occur in the school environment during the transition from elementary to junior and senior high school. After this transition, adolescents are confronted with a large and more diverse population of students, and one's status in this new setting is often based on being known by peers. Subsequently, many students speak of the need to expand their personal networks to avoid becoming lost and isolated in new school settings.

The importance of finding a position within larger friendship networks suggests that adolescents are particularly susceptible to peer influence during these transition years, including behavioral constraints that may pull them toward or away from problem behavior. This concern over locating position within the school hierarchy and gaining a sense of belonging among their peers leads students to

adopt a variety of strategies to enhance peer solidarity. For instance, girls may use gossip to direct and constrain behavior among peers, and boys may enforce masculinity norms such that behaviors emphasizing aggressiveness, dominance, and toughness are encouraged. These findings suggest that friendship networks and peers exert considerable influence over behavior during the adolescent years, including delinquency.

Despite the large body of research examining the importance of peers and peer behavior for delinquency, the contribution of peer relations to delinquency remains controversial, with different theories suggesting different reasons for the association between friends' and an individual's behavior. Next, theoretical explanations for the peer–delinquency association are summarized.

Theory

The two dominant perspectives on the causes of delinquent behavior are Hirschi's (1969) *social control theory* and Sutherland's (1947) *differential association theory*. Other theories that speak to the issue of peer delinquency include Gottfredson and Hirschi's (1990) *general theory of crime* and Osgood and colleagues' *opportunity theory* (Osgood, Wilson, O'Malley, Bachman, & Johnston, 1996). Although these theories offer useful explanations for understanding the importance of peer relations for delinquency, a social network perspective can offer additional insight through which to understand the role of friendship networks for delinquent behavior.

Social Control Theory

Hirschi's (1969) social control theory of delinquency is based largely on the notion of social integration and the idea that individuals form bonds to society that prevent them from acting on their delinquent impulses. In terms of friendship networks, social control theory posits that the more bonds an adolescent has through friendship ties, which carry a connotation of attachment, the less delinquent the adolescent will be.

One of the more problematic aspects of social control theory involves its neglect of the context in which the social bonds occur. Although research has established that in most cases social bonds through attachment are associated with a reduction in delinquency, these social bonds are not likely to reduce delinquency when adolescents are attached to delinquent friends. When an adolescent has delinquent friends, being attached to these friends is likely to direct behavior toward, not away from, delinquent behavior. Despite Hirschi's (1969) denial of the importance of delinquent peers, it is these delinquent associates who are implicated in the transmission of delinquency and to whom differential association theory attaches primary importance.

Differential Association Theory

Sutherland's (1947) differential association theory is based on the premise that delinquency is learned through intimate social relations with individuals whereby attitudes or "definitions" favorable to law violation are acquired. Not only are adolescents' attachments to peers important for delinquency involvement, but also, and more important, the context or norms of the friendship group determine whether attachment to friends results in conventional or delinquent behavior. According to Sutherland, the social transmission of delinquency occurs within the friendship network through the transference of attitudes about the appropriateness of delinquent behavior.

Whereas Sutherland's (1947) theory emphasizes the attitudes of peers in the transmission of delinquency, Akers's (1985) extension to differential reinforcement theory suggests that the adoption of delinquent behavior occurs through imitation of peers' behavior or through the observation of its consequences, either positive or negative. The important point made by these socialization theories, including differential association and social learning theories, is that delinquent behavior is learned through intimate personal relations, with friends serving as an important mechanism in adolescence by which delinquent behavior is observed and passed on.

Opportunity Theory

A third theory that is useful for understanding how peer networks influence adolescent behavior was offered by Osgood and colleagues (1996) in their opportunity theory. This position argues that situations conducive to delinquency are especially prevalent during time spent in unstructured socializing with peers in the absence of authority figures. This is because the presence of peers makes delinquent acts easier and more rewarding, the absence of authority figures reduces the potential for social control responses to delinquency, and the lack of structure leaves times available for delinquency. From this perspective, peer relations are not connected to delinquency by the type of friends that one chooses. Instead, what matters is the amount of time spent with peers engaged in a common type of activity. Friendship networks, according to this perspective, are important because they provide opportunities for adolescents to engage in delinquent behavior. Whether the friends are delinquent themselves is less important than the amount of time spent in unstructured activities with friends away from authority figures.

Self-Selection

An alternative perspective on the association between friends' delinquency and a adolescent's delinquency was offered by Gottfredson and Hirschi (1990) in their general theory of crime. The basic premise here is that peers have

no influence on delinquency; instead, stable characteristics of individuals determine how adolescents cluster together and therefore account for individual participation in delinquency (i.e., the idea that birds of a feather flock together). In particular, Gottfredson and Hirschi argued that adolescents' level of self-control (i.e., the ability to control impulsive behavior) determines whether adolescents self-select into delinquent or prosocial friendship networks. Because self-control is believed to be strongly associated with delinquent behavior, this position suggests that delinquent behavior precedes selection of delinquent friends (i.e., delinquent adolescents select other delinquent adolescents to be friend). At issue here is what comes first, an adolescent's delinquency or the delinquency of his or her friends.

A more nuanced position suggests that both socialization (i.e., peer influence) and selection (i.e., adolescents select friends similar to themselves) contribute to the similarity found between friends' and an adolescent's behavior. The theories of both Elliott and colleagues (Elliott, Ageton, & Canter, 1979) and Thornberry (1987) imply that delinquent peer groups and normative influence are reciprocally related, with both processes at work. Therefore, adolescents are likely to befriend others similar to themselves, and once friendships are formed, behavior is likely to be reinforced and shaped to be consistent with group norms.

Social Network Perspective

Although social control theory pays limited attention to the context in which social bonds occur, its focus on the constraining influence of social integration is consistent with a social network perspective. Being integrated within a friendship network in which adolescents are likely to report high attachment and time spent with peers either facilitates or discourages delinquency involvement depending on the norms, values, and behaviors evident in the network. Consistent with Eder and Enke's (1991) finding that although adolescents often discount a peer's evaluation, but never a group evaluation, is the notion that embeddedness within a social structure, such as a friendship network, acquires additional influence because it creates expectations for behavior while reinforcing the social norms and beliefs of the network. This idea of embeddedness also ties nicely into Sutherland's (1947) theory of differential association, because being enmeshed in a peer network provides access to expectations, norms, and sanctions that either support or discourage delinquent behavior. Because peer friendships are of central importance during adolescence, and considering that one of the most important developmental goals during this period is ensuring peer acceptance, peer networks should be especially effective at directing and constraining individual members' behavior.

Although a network perspective offers a particularly useful tool for understanding how peer networks can influence

behavior, research has until recently neglected to incorporate a network perspective to understand the role of peer relations in adolescent delinquency. As the next section illustrates, this has led to a limited understanding of the role of peers for understanding adolescent delinquency.

Methods

Despite the large body of research documenting the role of peer influence in adolescent delinquency, research on the role of delinquent peers has been limited in three important ways. First, past research has used a less than precise definition of the friendship group in which normative influence is believed to occur. Most studies in the criminology literature examining the effect of peer influence on delinquency have simply asked adolescents to think about their friends in general and to report whether their friends have participated in a particular illegal behavior or set of illegal behaviors. As a result of this strategy, it is unclear who was included in adolescents' definition of "friends." For instance, the number of friends considered is unknown. In addition, no information on prosocial individuals (i.e., friends who abstain from crime/delinquency) has been collected.

Second, problematic measures of peer influence have been used. For the most part, past research has relied on adolescents' perceptions of friends' behavior. Therefore, the standard approach to measuring peer delinquency contains a same-source bias that substantially inflates similarity in behavior between peers. In almost all criminological studies, information about friends comes from adolescents' descriptions of the behavior of their friends instead of from those friends' reports of their own behavior. Such measures inflate the similarity in behavior between adolescents and their peers, because people tend to project their own attitudes and behavior onto their friends, a phenomenon social psychologists refer to as *assumed similarity* or *projection*. Although such findings have led several scholars to caution against the use of adolescents' reports about peers, there has been limited recognition of this problem in research on crime and deviance. Such findings show that there is some truth in Gottfredson and Hirschi's (1990) argument that adolescents' reports of their peers' delinquency "may merely be another measure of self-reported delinquency" (p. 157).

Third, prior research has neglected to consider the role of the structural properties of friendship relations. By overlooking the structure of friendship networks, past research has assumed that everyone in the friendship network is affected by friends' behavior similarly. This is an oversimplification of network processes because it overlooks the adolescent's position within the network (e.g., central vs. peripheral), the cohesiveness of the network (i.e., the interconnections among network members), and the adolescent's prestige (e.g., popularity) within the network. These structural characteristics shape the degree to which adolescents are influenced by group dynamics.

Fortunately, recent work on social networks and network analyses has begun to make its way into the work of researchers interested in understanding peer processes as they relate to adolescent crime and delinquency. Much of this recent work has been spurred by the availability of a new novel data set, The Longitudinal Study of Adolescent Health (hereafter, *Add Health*), which allows researchers to overcome the limitations just described (for use of the Add Health data, see, e.g., Haynie, 2002). The advantage of these data is that they can be used to incorporate a social network perspective to elaborate on the normative influence process believed to generate peer similarity among friends. Specifically, a network perspective is guided by the assumption that the behaviors exhibited by network members, as well as the structure of the network, have important consequences for understanding subsequent behavior. In the context of delinquency, this suggests that exposure to pro- or anti-delinquent behaviors will depend upon the structure of the network, the adolescent's position within the network, and the behaviors exhibited in the network.

In addition, and in contrast to past measurement strategies, a network perspective offers a more desirable measurement strategy whereby the friendship network is carefully mapped out, responses about behaviors come directly from the friends' perspectives, and network homogeneity and structure are considered. The beginning point of network studies involves asking adolescents both to describe their own behavior and to identify their friends. The second step involves locating and interviewing the friends, with the friends describing their own behavior and then identifying their friends, and so on. In a best-case scenario, all adolescents and friends in the population of adolescents provide this information. This allows for the links among friends to be established for the purposes of constructing analytical friendship networks with identifiable structural properties and allows researchers to measure friends' behavior based on the actual responses of friends themselves.

Add Health Data

Part of the reason the effects of friendship networks on adolescents' delinquency has received less attention than it deserves is that the necessary data have not been available. Understanding social networks' influence on adolescent delinquency requires detailed data on the structure of friendship networks within a school, for many different schools. Until recently, the only data that approached these stringent requirements came from Coleman's (1961) landmark study of social relationship among high school students in the 1960s. Fortunately, more recent data are now available.

Add Health is a nationally representative sample of adolescents in Grades 7 through 12 located within randomly selected schools in the United States in 1995–1996. The innovative design of this sample, in particular its emphasis on the effects of multiple contexts of adolescents' lives, allows for an examination of the causes of adolescent

health and health behavior (including delinquency) that goes considerably beyond prior research.

Adolescents were included in the Add Health study on the basis of a sampling design that stratified schools by region, urbanicity, school type, ethnic mix, and size. This is important because, when used properly, these data allow findings to be generalized to all adolescents enrolled and attending middle and senior high schools in the United States. In addition, the data are longitudinal and currently consist of three waves of data: an initial in-school questionnaire followed by three in-home surveys conducted in 1995, 1996, and 2002.

Information collected in the in-school questionnaire is the critical component of the study for network analyses, because this is where the friendship networks of school-age adolescents are measured. In the initial in-school survey administered in 1994–1995, all students attending school on the day of the self-administered questionnaire in each of 132 high schools and middle schools were surveyed. This sample is the basis for the construction of the measures of friendship network characteristics. To tie all of the students together in the schools, researchers asked each student who filled out the in-school questionnaire to nominate up to 5 of his or her closest female and 5 of his or her closest male friends (for a maximum of 10 friends). They identified their friends by name from school rosters and entered a corresponding identification number. Because each student in the school was interviewed, global networks (i.e., school networks connecting all students in the school) were re-created. The behaviors of friends nominated by the adolescent, as well as those friends who nominated the adolescent, were matched to the adolescent's record, allowing a unique opportunity to assess the actual effect of friends' behaviors.

Friendship networks can be defined in various ways using the Add Health data. For instance, it is possible to define the network as consisting of those adolescents who reciprocate the friendship nomination (i.e., the friendship network contains only adolescents whose friendship ties sent to others are reciprocated), as containing only those nominations sent to others (i.e., including only those friends that the adolescent nominates), as containing only those nominations received from others (i.e., including as friends those adolescents in the school who nominated the adolescent as a friend), or as including both ties sent and received (i.e., defining the friendship network as including all of those friends the adolescent nominated as well as those adolescents in the school who nominated the adolescent in the school). In addition to examining characteristics of the adolescent's friendship network (including behavior, demographics, and structure), these data make it possible to measure characteristics of the overall school network in which the adolescent's friendship network is located.

Following the in-school questionnaire, in-home surveys were administered to a smaller sample of adolescents selected from school rosters and involved a longer series of questions, including items concerning more serious delinquency involvement. By the time of the third wave of data

collection, the sample was approaching young adulthood (i.e., between the ages of 18 and 26). Unfortunately, network information for all students was available only during the initial in-school questionnaire. However, for a small number of schools, network data are available for two points in time. Because of Add Health's interest in social networks, there were 12 schools from which all enrolled students were selected for the in-home interviews (instead of a random sample). The 12 schools (2 very large schools and 10 small schools) have various characteristics, including location in rural and urban areas, designation as public and private schools, and differing degrees of ethnic heterogeneity. In this saturated sample, all adolescents in these schools were interviewed in depth in their homes. In addition to answering a series of questions relating to involvement in serious delinquency, students in these schools also nominated their closest friends at two points in time (during the first and second in-home interviews). These data, therefore, provide a unique opportunity to study the effect of peer influence processes over time. More information on the Add Health data design can be found at the following Web site: <http://www.cpc.unc.edu/projects/addhealth/design>.

Applications

Although much is known about the relationships between delinquency and friends' behavior, only a few studies present detailed information on friendship characteristics among delinquent adolescents. Warr (1996) examined specific features of delinquent subgroups, such as group organization and the instigator role within groups, and determined that the structure of the group, not an individual's attributes, affects which individual instigates delinquency. Results from his study also indicate that groups are more specialized in terms of delinquency involvement than individuals tend to be, so that most delinquent offenders belong to multiple groups, with each group specializing in a smaller range of offenses. This latter finding also highlights the multifaceted nature of peer groups; individuals in school settings can be members of many different friendship groups and face differing degrees of constraint depending on whether the behavior, norms, and values of the group coincide or diverge. This is consistent with Dunphy's (1963) finding that most adolescents do not belong to a single, densely knit, isolated friendship group but instead are affiliated with many loosely bounded friendship groups with varying degrees of cohesion and permeability.

Although delinquency is largely a group behavior, there is evidence that some offenses are more likely to occur in groups than others. For instance, offenses including the use of alcohol and marijuana and vandalism are more likely to be committed in groups compared with offenses such as assault and shoplifting, which are among the offenses least likely to be committed in groups (Warr, 1996).

The nature of friendship relations in delinquent versus nondelinquent networks has also been developed in two influential studies. Giordano, Cernkovich, and Pugh (1986)

found that various dimensions of friendship relations do not differ markedly between delinquent and nondelinquent adolescents. Both delinquent and nondelinquent youth report similar levels of attachment, intimacy, and contact with friends. Kandel and Davies (1991) also found few differences in the quality of friendship relationships among adolescents who did and did not use illicit drugs.

Despite original emphasis on the importance of exposure to definitions or attitudes favorable to law violation, prior research has consistently indicated that attitude transference is not the primary mechanism through which friends influence one another; instead, adolescents appear more influenced by the behaviors of friends than they are by friends' attitudes toward crime (Warr & Stafford, 1991). Consistent with social learning explanations of peer influence, these findings suggest that imitation of friends' behavior and direct reinforcement of behavior by friends are most important (Akers, 1985).

Even though the studies just described are important for considering the role of peer relationships for adolescent delinquency, they were not able to draw on detailed social network data to ask more varied questions about the role of friendship networks. To do this, work using the detailed friendship networks available in the Add Health data has begun.

Recent work by Haynie illustrates some of the beginning questions that researchers interested in adolescent delinquency can address using network data available from Add Health. A popular issue in the field of criminology has been trying to understand whether adolescents select into delinquent peer groups on the basis of their own behavior (as Gottfredson & Hirschi, 1990, suggested), supporting the common adage that birds of a feather flock together. If this idea is true, then friendship networks should exhibit predominately delinquent or nondelinquent behavior. This, therefore, raises the question: Do adolescents have homogeneous networks in terms of the delinquency of their friends?

Using friendship network information available in the Add Health and a dichotomous measure of delinquency (1 = yes, adolescent engaged in some delinquency during the past year; 0 = no delinquency reported), Haynie (2002) found that adolescents are located in rather heterogeneous networks in terms of the display of delinquent behavior; that is, the most common pattern is for adolescents to have both delinquent and nondelinquent friends in their friendship networks. Specifically, she found that 56% of adolescents are in a mixed network, with both delinquent and nondelinquent peers; 28% are in an entirely delinquent network; and 16% are in an entirely nondelinquent network.

These findings suggest that peer networks are much more heterogeneous in terms of exposure to delinquent friends. Although there is some evidence that delinquents cluster together, most adolescents in schools have both delinquent and nondelinquent friends in their networks of close acquaintances. This is an important finding that is at odds with Gottfredson and Hirschi's (1990) assertion that self-selection is entirely responsible for the peer–delinquency association, because the assumption is that there are clearly delineated

delinquent or nondelinquent networks that adolescents choose to join. Instead, most adolescents are exposed to both delinquent and nondelinquent patterns, and the ratio of these patterns influences behavior. When friendship networks contain access to both delinquent and nondelinquent friends, the network may be less effective in providing clear behavioral guidelines, cohesive norms, and consistent values regarding behavioral expectations.

A second common question concerns whether peer delinquency influences subsequent behavior or instead results from selection processes or the tendency for adolescents to project their own behaviors onto the peers whom they think of as their friends. The Add Health data provide a unique opportunity to address this question, because, as discussed earlier, the methodological structure permits the careful definition of friendship networks. With this approach, results based on the Add Health data suggest that peer delinquency is associated with an adolescent's subsequent delinquency, controlling for prior delinquency; however, the effect is much smaller than that estimated by prior research that did not incorporate a network method and perspectives (Haynie & Osgood, 2005). This finding suggests that relying on adolescents' perceptions of friends' behavior does introduce substantial same-source bias that inflates the correlation between friends' and adolescents' behavior.

Third, recent work has been able to ask whether network characteristics condition the strength of the peer–delinquency association. In addition to measures of network behaviors, Add Health data allow for assessment of the structure of peer networks and the location of an adolescent's position within the friendship network. Three network characteristics in particular appear to shape the degree of influence operating in a friendship network: (1) the density of ties within the network indicating how cohesive the network is, (2) the centrality of the adolescent's position in the network, and (3) the popularity of the adolescent within the network. Specifically, it is expected that peer delinquency will have a stronger influence on an adolescent's behavior when the friendship network is very dense (i.e., the adolescent's friends are friends with one another), when the adolescent is located in a central position (vs. a peripheral position at the edge of the network), or when the adolescent has high prestige in the network (i.e., when he or she is very popular and receives many friendship nominations from others in the school). Findings based on the Add Health data suggest that this is indeed the case. In particular, network density emerges as an important component of the peer–delinquency association, with very cohesive networks promoting greater influence than networks that are less cohesive (Haynie, 2001).

If delinquency is largely a group phenomenon, then what would we expect to find in regard to delinquent behavior for adolescents who are isolated from peers? This is the interesting question that Kreager (2004) tackled using Add Health data. Theories reviewed earlier in this chapter suggest competing hypotheses about these isolated individuals. According to socialization theories (differential

association and social learning), isolated adolescents will have limited access to delinquent role models and, as a result, are expected to engage in low or no amount of delinquency. In contrast, social control theory would expect that the lack of attachment to friends would result in individuals who are more inclined to act on their delinquent impulses. Kreager's results indicate that although isolation from peer friendships is a rare event (less than 5% of the sample were friendless), its relationship to delinquency is more nuanced than socialization or social control theories would predict. Isolates who do not report peer trouble have very low levels of delinquency; however, isolates who also report peer conflict are likely to report higher levels of delinquency. Therefore, the effect of peer isolation on delinquency depends on whether adolescents report peer conflict.

In addition to facilitating examination of the peer–delinquency association, the Add Health data allow researchers to examine network behaviors and network structures as important mediating variables in explaining outcomes of interest (e.g., delinquency). For instance, in the criminology literature, there has been a common finding that girls who experience pubertal development earlier than their peers are at increased risk of engaging in subsequent delinquent behavior. One reason for this increased risk is the differing peer networks in which more developed versus less developed females find themselves. In particular, research using the Add Health data has found that females who experience pubertal development earlier than their peers do have higher levels of delinquency 1 year later, but this is because these girls are at heightened risk of being involved in romantic relationships and because their friends are engaging in risky behaviors (Haynie, 2003). This suggests that peer networks serve as a mechanism that differently place certain groups of adolescents at heightened risk of problem behaviors.

Future Directions

This chapter highlights some of the research questions that have addressed the relationship between peer networks and delinquency, but it is also important to consider future research directions that need to be explored further.

Although this chapter has emphasized the important context of adolescent friendships, future research would benefit greatly by incorporating multiple dimensions of potential influence. In particular, the delinquency involvement of other key individuals in youths' networks, such as romantic partners, siblings, parents, and neighbors, may add to our understanding of influence processes. Because research has highlighted the importance of competing prosocial and deviant friendships that make up the bulk of adolescents' friendships, it is likely that other influential persons beyond friends could tilt the ratio of definitions favorable versus unfavorable to delinquency involvement. Incorporating these multiple contexts of adolescents' lives into future analyses would also increase our understanding

of the relative risk factors that adolescents face and potentially provide avenues toward reducing these risk factors.

Comparing the strength of influence across relational contexts also can provide unique insight into adolescents' overall susceptibility to delinquent patters. One example of research that incorporated romantic partner behavior is that by Haynie, Giordano, Manning, and Longmore (2005), which shows that romantic partners' delinquency exerts a unique effect on adolescents' delinquency, over and beyond that of friends' delinquency and control variables. In addition, recent work has compared the influence of "best friends" to that of youth considered "close friends" (Weerman & Smeenk, 2005). Taking this further, it would be interesting to also consider influence deriving from that of the overall school network in which adolescents are enmeshed. Along these lines, future research could identify the most popular students in the school to determine whether their behavior is especially influential for other individuals located in the school (who may or may not be tied to the most popular students).

Future research should also consider whether and how peer influence varies across demographic groups, such as by gender and race. On the basis of studies of homophily in friendship choice and evidence that race is one of the most important characteristics that influences which friendships form, we might expect to find that African American youth are more likely to be found in mixed networks where definitions toward delinquency are less clear-cut. In terms of susceptibility to delinquency by race, prior evidence suggests mixed findings. In terms of gender, research suggests that although girls place more emphasis on close friendships incorporating intimacy and closeness than do boys, there is some evidence that boys are more susceptible to peer influence (Giordano et al., 1986). Other research suggests that gender differences in peer influence depend on the sex composition of the friendship network (Haynie, Steffensmeier, & Bell, 2007).

Another avenue for future research involves incorporating the school and neighborhood context to better understand how social environments make unique contributions to the levels and severity of delinquency found among individuals and in their networks. Neighborhood and school environments are especially likely to determine the exposure adolescents have to prosocial or delinquent others. In addition, school factors such as school size, school disciplinary practices, school climate, school resources, and school policies such as tracking are likely to produce environments more or less conducive to delinquency and/or to place delinquent youth in closer proximity to other delinquent youth. This information would allow researchers to ask whether delinquent behavior among friends is more likely to occur in disadvantaged or disorganized schools, for example.

In addition, researchers may be interested in whether and how characteristics of the overall global school network (e.g., the density of ties, the racial heterogeneity of ties) influence levels of delinquency in the school. For instance, this type of information can be used to identify school characteristics that are most likely to suppress

delinquency and/or violent behavior in the school, reduce the transmission of delinquent behavior, and/or decrease opportunities for high-risk youth to cluster together. In sum, future research should pay more explicit attention to the ways that neighborhoods and schools shape adolescent friendship networks, which in turn provide the contexts in which peer influences appear to flourish.

Future research should begin to examine how friendship networks and behavior change over time in school contexts. For example, researchers should consider the question of what predicts the dissolution of friendship ties over time. According to socialization theories, an individual's behavior is shaped by the group norms to which youth are exposed. In the case of friendships, what happens when the behavior in question is not displayed by all members of the group? The normative influence process could sway the group's behavior in favor of or against the behavior in question. Perhaps there is a tipping point at which it becomes more likely for the group to adapt the behavior in question or members who are not displaying the behavior to select out of the group (i.e., the tie is dissolved). These are interesting questions that could be addressed using longitudinal network data available.

Finally, future research needs to attempt to identify the mechanisms responsible for transmitting peer behavior to individuals. Although socialization theories suggest a variety of mechanisms that are potentially responsible, research has yet to clearly identify the specific ways that networks influence behavior. For instance, does the effect of peers on subsequent behavior result from social capital generated in the group, the modeling of group processes, increased opportunities for delinquency, deterrence factors, or a mixture of these mechanisms? Precise identification of the mechanism underlying behavioral similarity may require a different methodological approach.

Conclusion

The purpose of this chapter was to elucidate the importance of peers and peer networks for understanding adolescent delinquency and crime. The network framework described in this chapter emphasizes the social connections among adolescents that goes considerably beyond prior research, which has viewed individuals as essentially separate from their social structure. Instead, the purpose here was to demonstrate the need for a network reformulation of the peer–delinquency association that incorporates characteristics of the friendship network in which adolescents are enmeshed.

As this chapter illustrates, not all adolescents are influenced to the same degree by their peer associations and, when the patterning of relationships between adolescents provides more opportunities for interactions among members (e.g., when the friendship network contains a higher proportion of delinquent youth or the network is very cohesive), peer delinquency plays a larger role in the adolescent's own delinquency behavior. This positioning in the peer network provides different opportunities for peer interaction,

resulting in varying exposure to delinquent behavioral models, communication of delinquent norms, access to information on delinquent opportunities, and opportunities for rewards or deterrents to delinquency.

Because research using network methods and data has found that the average adolescent is exposed to both delinquent and nondelinquent friends and that adolescents' own delinquency level is associated with the proportion of delinquent friends in the network, any intervention policies that bring delinquent youth together for targeted intervention may have unintended negative consequences. For instance, these policies are likely to exacerbate problem behavior if social influence occurs and deviancy training takes place in these settings (see, e.g., Dishion, Spracklen, Andrews, & Patterson, 1996). Although network studies of adolescents are more costly to implement, the findings emerging from such research suggest that interventions are more likely to succeed (i.e., to reduce problem behaviors) if they are able to minimize exposure to delinquent peers.

In addition, identifying adolescents most at risk of being influenced by peer dynamics and/or transmitting delinquent behavior to others can be useful information for policies aimed at reducing delinquent behaviors, because they can help to identify where school resources may have the greatest impact. For instance, it may be important not only to target delinquent peer networks but also to focus on the delinquent peer networks in which density is high or in which adolescents are located in central positions.

In sum, the approach of identifying and examining peer social networks provides a coherent and promising framework for investigating a variety of ways that peers shape and influence adolescent involvement in delinquency and crime. This conclusion is consistent with the current emphasis on the significance of social contexts (e.g., neighborhood, school) and suggests that an important context with important implications for adolescents' behavior is the peer networks in which youth are embedded.

RACE/ETHNICITY AND CRIME

MATTHEW PATE

State University of New York at Albany

WILLIAM C. PLOUFFE JR.

Kutztown University

The meaning of *race* has changed significantly over the course of human history. Early theories of race assigned numerous social, intellectual, moral, and physical values to the apparent differences between groups of people. From the 17th through early 20th centuries, the study of race was defined in terms of a hierarchy of putative biological differences. In this era, scholars working from various social and natural science perspectives developed “scientific” justifications that were subsequently used to rationalize the disparate treatment of ethnic, racial, and social groups. In the decades following World War II, the concept of race increasingly came to be understood more as a social and political construction and less as a matter of biology. A considerable body of modern theory regards race as a social mechanism used to preserve unbalanced relationships of power. In this chapter, readers will encounter a brief history of race as a subject for social thought, followed by a review of more recent developments in criminological theory. Last, a discussion of race as a component of social policy with specific regard to its place in American legal history is presented.

Before one can meaningfully discuss the instrumental properties of race in a social context, a definition of the concept itself must be developed. That said, the reduction of race to a single essentialist criterion is a difficult, if not impossible, endeavor. Although phenotype or skin color may strongly inform racial categorization, historically many other characteristics have been treated as equally determinative. National or ethnic origin, social class, religion, and language

have all been used to identify racially “distinct” groups. Race is thus invested with a complex social context that depends in part on the prevailing “common understanding and meaning” of society (*In re Ah Yup*, 1878).

Lopez (1994) defined race as follows:

A vast group of people loosely bound together by historically contingent, socially significant elements of their morphology and/or ancestry . . . an ongoing, contradictory, self-reinforcing process subject to the macro forces of social and political struggle and the micro effects of daily decisions. (p. 3)

Although this is but one scholar’s attempt to capture the attributes of an admittedly difficult concept, this definition speaks to the malleability of the term and its predominantly social, rather than biological, construction.

It is difficult to pinpoint a time in history when theories of race were first used as a tool to categorize people. Some scholars argue that the process of racial categorization, as well as the assignment of relative social values to those categories, was prevalent by the end of the Middle Ages in Europe (Winant, 2000) and by the Renaissance in England (Bartel, 1997). Sweet (1997) made the following argument:

By the time of the Columbian encounter [with the peoples of the New World] . . . race, and especially skin color, defined the contours of power relationships. . . . Biological assumptions that were familiar to a nineteenth-century Cuban slave owner would have been recognizable to his fifteenth-century Spanish counterpart. (p. 166)

Winant (2000) added the following:

The Crusades and the Inquisition and the Mediterranean slave trade were important rehearsals for modern systems of racial differentiation . . . in terms of scale and inexorability, the race concept only began to attain its familiar meanings at the end of the middle ages. (p. 45)

Less than a century ago, Italian, Irish, and southern European immigrants and their descendants were considered by many other Americans as “non-white” (Ignatiev, 1996). Oxford professor Edward Freeman espoused a prevalent late 19th-century viewpoint with the statement, “The best remedy for whatever is amiss in America would be if every Irishman would kill a Negro and be hanged for it” (Tucker, 1996, p. 34). The social status of “whiteness” was eventually conveyed on many of these immigrant groups on the basis of changes in social agreement regarding their assimilatory potential combined with the establishment of a racial identity appropriately distanced from their “blackness.” Lopez (1996) documented more than four dozen American legal decisions from 1878 to 1952 in which individuals representing various nationalities and ethnic groups had their relative “whiteness” determined in court.

As social and legal conceptions of race have evolved, an important point has emerged: Race is a matter not just of discerning group characteristics but of understanding and demarcating social relationships. The history of scholarship regarding race speaks directly to this point.

A Brief History of Race

The first conflict between one human group against another is a matter lost to history. Equally distant is the first enslavement of a defeated people by their conquerors. Even so, our modern language is peppered with pejorative terms referencing ancient conflicts. For instance, we understand colloquially what it is to be a “barbarian”; however, most of what we know about the actual “barbarian races” that plagued Greek and Roman society comes from the written records of the Greeks and Romans themselves. The Greek historian Herodotus made the following observation:

Their lust for gold is immense, their love of drink boundless. Barbarians are without restraint . . . they are given to gross personal hygiene. . . . Their reproductive energy is inexhaustible . . . [if] driven back or destroyed, another already emerges. . . . Indeed, there are no new barbarian peoples . . . descendents of the same tribes keep appearing. (Wolfram, 1992, pp. 6–7)

As Winston Churchill once quipped, “History is written by the victors.” In this case, as with many others, the victory need only be cultural, not military.

Etymologically speaking, the Greek root of the term *barbarian* means “strange, foreign or ignorant.” Thus, one sees that human history has long been shaped both politically and linguistically by negative reference to a defeated or marginalized “alien.” This kind of semantic (or actual) distancing of one group by another has played an important part in social policy throughout human history.

One of the first instances when a systematic consideration of race was used to inform modern European public policy is found in the 17th-century writings of Gottfried Wilhelm Leibniz. In 1671, Leibniz proposed the *Consilium Aegyptiacum*, or “Egyptian Plan” to King Louis XIV of France. In this scheme, an army of “semi-beasts” composed of slaves taken from “Africa, Arabia, Canada, New Guinea . . . Ethiopians, Negroes, Canadians, and Hurons” would be collected and trained as an elite force to be used for world conquest (Fenves, 2006, p. 14). Interestingly, the racial classification system Leibniz used relied primarily on religious distinctions (Christian vs. non-Christian) instead of phenotype or skin color to justify the enslavement of non-Europeans.

Although Leibniz put forth a very rudimentary theory of race based on religious and geographical criteria, the first detailed racial taxonomy of humans was advanced by the Swedish biological taxonomist Carolus Linnaeus in his 1735 work *Systema Naturae* (Uppsala Universitet, n.d.). Linnaeus divided human beings into four distinct categories based on skin color and geographical origin: (1) Europeus (white), (2) Africanus (black), (3) Americanus (red), and (4) Asiatic (yellow). Each of these categories was described in terms of personal, mental, and physical attributes said to typify members of the respective groupings.

In an effort to promulgate a uniform theory of race, the German medical doctor and physiologist Johann Friedrich Blumenbach in 1775 proposed a racial classification scheme that proved very influential even into the modern era (Zammito, 2006). Blumenbach was vehemently opposed to viewing groups of humans as “different species.” He asserted that differences in complexion and phenotype were caused by climate. Blumenbach also protested against theories of racial superiority. As he observed, “[While non-Europeans may be different in color,] as a whole they seem to agree in many things with ourselves” (Zammito, 2006, p. 47).

The racial theories of Blumenbach and other social philosophers gained particular significance during the Age of Enlightenment. Likewise, the Aristotelian conception of “natural order” regained intellectual currency; and as an extension of this ordering, the “inherent” inequalities therein implied were used to rationalize the subordination of groups deemed “inferior” (Tucker, 1996, p. 10). Enlightenment thought heralded a move away from an understanding of human identity couched in religion and preservation of the nobility through biological understandings of lineage, to an identity vested in the context of race (Goldberg, 1993).

Paradoxically, as Malik (1996) argued, Enlightenment ideals of reason, rationality, and the scientific method do not necessitate understanding human difference in terms of race; instead, he contended that Enlightenment faith in reason, empiricism, and human equality were applied to justify entrenched social inequalities in terms of racial difference. Even as members of the poorer classes called for recognition of universal rights, dominant social forces provided a strong response. Universal rights were seen as directly oppositional to bourgeoisie notions of capitalism and the emerging free markets that displaced the old feudal and monarchic order. The inherent inequality stemming from the private ownership of property led thinkers such as Adam Smith (1789/2003) to conclude a necessity for limits on and exceptions to “universal equality” as a means to protect the “natural” rights of propertied classes.

As the world moved through the age of revolution and into the 19th century, the defense of private property as a natural right of humankind necessarily required a more nuanced concept of social equality. More than at any point in human history, a fundamental paradigm shift was poised to take place. The divide between a person’s natural right to social equality and freedom versus the natural right to own private property came to foment over the issue of slavery. Slavery was regarded as a form of private property and took its primary justification not on grounds of racial inequality per se but as a matter of economic necessity. Slavery was regarded as a “necessary evil” to support general economic progress and provide opportunities for poorer whites (Malik, 1996, p. 67). As discussed in a following section, the American experience of reconciling these interests has been as troubled and protracted in the courts as it was bloody on the battlefields of the Civil War.

The preceding treatment of race as an evolving social construct demonstrates several fundamental relationships that social scientists in the 20th and 21st centuries have used to examine race, crime, and social policy. First, the distinctions of race have, from first delineation, been used to inform public policy. Second, science has repeatedly been called upon to justify, with reference to “natural order” or “necessity,” the social and economic hierarchies present in society. Last, numerous criteria, including skin color, phenotype, religion, language, social class, geographic origin, and so on, have been used to substantiate purported racial differences and the social inequities predicated thereon.

Race and Modern Criminological Theory

Although an arguable amount of progress has been made in the general academic treatment of race, the intersection of race and crime still proves to be a problematic topic for social science. As Sampson and Wilson (1995) stated, “The discussion of race and crime is mired in an unproductive

mix of controversy and silence . . . criminologists are loathe to speak . . . for fear of being misunderstood or labeled racist” (p. 37). Nonetheless, the disproportionate involvement of minorities with crime, both as victims and perpetrators, demands a systematic and balanced exploration. Many social scientists (Mann, 1993; Stark, 1990) complicate the matter with assertions that the perceived differential between groups with regard to crime is reducible to either systematized bias or unreliable/misapplied statistics. To counter, a number of scholars (Hawkins, 1986; Hindelang, 1978; Katz, 1988; Sampson & Wilson, 1995) have provided arguments that both acknowledge the differentials while furthering the etiological debate.

As the preceding discussion implies, there are many divergent perspectives on the matter of race and crime. Accordingly, there is little broad agreement on many of the fundamental aspects of the issue. This said, it is instructive to consider some general theoretical categories of scholarship and how each has addressed the problem.

Among the oldest body of work that considers the matter of race and crime may be those which are described as *sociobiological theories*. These theories generally posit that criminality (or the proclivity thereto) is a matter of hereditary, genetic, or physiological flaw. Perhaps the most well-known of these is the work of Cesare Lombroso. Lombroso (1912/2006) proposed that criminals were a kind of evolutionary throwback to a more primitive condition: “The criminal is an atavistic being, a relic of a vanished race . . . a return to characteristics peculiar to primitive savages” (p. 21). Lombroso’s work spawned an examination of theorized physiological and psychological differences between criminals and “normal” people. Lombroso famously observed that “many criminals have outstanding ears, abundant hair, a sparse beard, enormous frontal sinuses and jaws, a square and projecting chin, broad cheekbones, frequent gestures, in fact a type resembling the Mongolian and sometimes the Negro” (p. 29).

In more recent years, Jeffery (1979, 1990) and Fishbein (1990) have proposed a revised version of sociobiological criminological theory. Jeffery’s (1990) work in particular concerns the interaction of genetics with environmental forces: “Genes influence behavior through pathway mechanisms such as the brain, brain chemistry and hormonal systems, all in interaction with one another and with the environment” (p. 184). Balkan, Berger and Schmidt (1980) were highly critical of this approach, calling it “a continuation of the tradition of looking for individual biological basis of criminal behavior” (pp. 18–19). Although Jeffery never expressly addressed race, adherents to the perspective nonetheless have cautioned against “the premature application of biological findings” (Fishbein, 1990, p. 55).

An individual-level theory that does expressly consider race is found in the work of Poussaint (1972). Poussaint’s theories consider the impact of rage and low self-esteem as conditioned by the African American experience: “Many of the problems in the Black community

are related to institutional racism, which fosters a chronic lack of Black self-respect, predisposing many poor Blacks to behave self-destructively and with uncontrollable rage” (p. 163). The “incessant . . . [irritation] of the black man’s psyche” (Guterman, 1972, p. 231) and “estrangement, cynicism and expectations of double-dealing” (Heilbrun & Heilbrun, 1977, p. 370) add support to frustration–aggression theory. Likewise, Bernard (1990, p. 74) refined the perspective by suggesting that social factors such as urban environment, low social position, and discrimination exacerbate the conditions noted in previous studies. As Bernard’s work suggests, understanding the interplay between the individual and his or her environment is important in assessing the relationship between crime and race.

Moving beyond individual-level theories, a number of perspectives have considered the impact of culture and the broader social environment in their explanations of crime and race. Hereto, there exists considerable debate. As Sampson and Wilson (1995) stated, “[Criminologists] have reduced the race-crime debate to simplistic arguments about culture versus social structure” (p. 38). As Sampson and Wilson correctly identified, the discourse is fundamentally one couched in either a “relative deprivation” structuralist hypothesis as typified by Blau and Blau (1982) or an equally unsatisfying cultural focus on “an indigenous culture” of ghetto violence offered by Wolfgang and Ferracuti (1967).

Of the two, the subculture-of-violence perspective is arguably the more widely discussed. In their elaboration of the theory, Wolfgang and Ferracuti (1967) sought to explain minority violence in terms of dominant subcultural values, which include “a potent theme of violence” that is transmitted through “lifestyle, the socialization process, [and] the interpersonal relationships of individuals living in similar conditions” (p. 140). A more recent explication of the subculture-of-violence perspective came from Luckenbill and Doyle (1989), who put forth the hypothesis that “young adults, males, blacks, lower income persons, and urban and southern residents are more likely than their respective counterparts to name a negative outcome, to claim reparation and to persevere and use force in resolving a dispute” (p. 425).

The subculture-of-violence perspective has garnered a substantial amount of criticism. Mann and Selva (1979) criticized the perspective for its over-focus on “the street lifestyle.” Haft-Picker (1980) summarized a number of concerns with her statement that “criminologists no longer agree on what the subculture of violence actually is or whether it exists at all” (p. 181).

In many regards, ecological theories of crime overcome the problems inherent to individual-level and subcultural explanations. As a general construct, ecological theories seek to identify and understand those features of communities, in particular urban communities that produce differential rates of crime (Bursik, 1988; Byrne & Sampson, 1986; Sampson & Wilson, 1995; Short, 1985). In particular,

the community-level approach first elucidated by Shaw and McKay (1942/1969) identifies three structural factors that contribute most strongly to juvenile delinquency: (1) low economic status, (2) ethnic heterogeneity, and (3) residential mobility. Perhaps their most prescient finding was their demonstration that high rates of delinquency persisted in certain areas irrespective of population turnover. This finding led Shaw and McKay to reject individualistic theories of delinquent behavior in favor of studying the process of intergenerational transmission of delinquency (and crime generally) in more socially disorganized areas (p. 320). Shaw and McKay directly refuted contemporary theorists (i.e., Jonassen, 1949) who argued that ethnicity had a direct effect on observed rates of delinquent behavior.

As pertains specifically to considerations of race, the social disorganization perspective founded largely in the work of Shaw and McKay (1942/1969) continues to be among the most fecund in the study of crime. Of particular note is the work of Messner and Sampson (1991), Sampson (1987), Sullivan (1989), and Meares (1998) on the influence of family structure and disruption in minority communities.

Perhaps the most damaging criticism of the social disorganization perspective, namely, that it is founded in circular reasoning, was summarized by Bohm (1997): “That is, social disorganization is the cause of delinquency, and delinquency is an indicator of social disorganization” (p. 78). Bohm also noted that the social disorganization perspective fails to account for high crime rates in stable working-class communities.

The work of Blau and Blau (1982), mentioned earlier, has inspired explanations of crime through the lens of economic and racial inequality. The influence of extralegal factors (e.g., economic inequality) on the social control of crime is the focus of considerable scholarly debate. The mass of the discourse is built around issues of race and social class examined from a conflict perspective (Eitle, D’Alessio, & Stolzenberg, 2002, p. 557). Liska (1987) asserted that “law making is assumed to reflect the interests of the powerful; those activities are criminalized that threaten their interests” (p. 77). Racial threat theory expands on the conflict perspective to suggest that law violations by racial minorities can be perceived as particularly threatening to those in power and will therefore be met with greater force (Liska, 1987, p. 77).

Blalock (1967) is generally viewed as the primary exponent of racial threat theory. Blalock argued that one may use the relative minority population size to predict the ways in which a majority population will exercise social control. According to his perspective, as the percentage of non-whites increases, they are perceived to constitute a political and economic threat to the white majority. The growing minority in essence “forces” members of the white majority to compete for jobs and other economic resources. As the minority population grows, it competes with whites for social resources, such as political power.

Racial discrimination is, according to this perspective, an attempt by whites to subvert racial minority efforts to exercise power. As an extension of this perspective, those things that become criminalized, and the ways in which the criminal justice system is structured to respond, reflects the interests of the majority population and its attempts to preserve social power.

Numerous studies support the conclusion that the size of the minority population influences social control (Bobo, 1983; Chamlin, 1989; Fossett & Kiecolt, 1989; Giles & Evans, 1986; Giles & Hertz, 1994; Glaser, 1994; Matthews & Prothro, 1966; Taylor, 1998; Wright, 1977). Despite this consensus, critics have identified a number of problems that undercut the racial threat perspective.

Liska (1987, p. 78) provided one of the more damaging critiques. Citing problems of “epistemic and theoretical linkage,” he contended that theorists have generally failed to properly operationalize and connect concepts such as “ruling class interests” and “threat.” Moreover, he held that the problems extend throughout the literature, for the following reasons:

Because the critical causal variables are not well defined, theoretically and operationally, and are not clearly linked to each other in the form of propositions or a causal model, the relevant research literature is also not well defined and integrated. (p. 78)

As readers can see, there are numerous theoretical perspectives through which one might approach the topic of race and crime. Each contributes to the broader understanding of the matter while presenting methodological or structural issues that remain to be reconciled. In this, one may view the body of criminological theory as a continually evolving construct. As readers will see in the following section, this metaphor of evolution also fits the history of American legal process with regard to race.

Race in American Legal History

One of the most difficult areas of American legal and political history has been the conjunction of race and crime. Matters of race have tainted legal proceedings and enforcement of the criminal law since before the founding of the United States of America. An examination of constitutional, judicial, and legislative history provides an understanding of how a person’s race has determined the extent of justice individuals were or were not allowed.

Before the Civil War

The U.S. Constitution, as originally enacted, recognized that those persons who were not free (i.e., slaves) were not endowed with the full rights of citizenship. For example, in determinations of congressional representation, slaves counted as only three fifths of a free person (U.S. Const.,

Art. I, Sec. 2, Cl. 3). Furthermore, when a slave escaped the captivity of a state permitting slavery, the law mandated the slave’s return to the slave state (U.S. Const., Art. IV, Sec. 2, Cl. 3).

Not until after the Civil War was the institution of slavery effectively abolished in the United States. The Thirteenth Amendment, which prohibits slavery, was enacted in 1865. This was followed shortly by enactment of the Fourteenth Amendment in 1868. The Fourteenth Amendment was extremely important in that it guaranteed “equal protection of the law to all persons; and that no person shall be deprived of life, liberty, or property without due process of law.” It further mandated that these principles were applicable to the states and not just to the federal government. Combined with the Thirteenth and Fifteenth Amendments, the Fourteenth Amendment was a statement of principle that race should not be a factor in denying any person justice. Moreover, the Thirteenth and Fourteenth Amendments, taken together, obviated the unequal three-fifths rule for determining the number of congressional representatives. The Fourteenth Amendment, did, however, stipulate that the required population count “[exclude] Indians not taxed.” With the adoption of the Fifteenth Amendment in 1870, the right to vote was guaranteed to all men over 21 years of age, regardless of race.

Such constitutional statements of principle were admirable improvements, but meaningful execution of policy was entirely another matter. In the decade following the Civil War, Congress took a number of steps to put policy into action. Congress passed the Civil Rights Act of 1866 (14 Stat. 27), which mandated equal property rights for all persons regardless of race. The Civil Rights Act of 1870 (42 U.S.C. § 1981) granted the right to contract to all persons regardless of race. It also provided criminal penalties for certain civil rights violations. The Civil Rights Act of 1871, also known as the Ku Klux Klan Act, provided for a civil action: to enforce violations of civil rights by the government (42 U.S.C. § 1983), to obtain damages for conspiracies to violate civil rights (42 U.S.C. § 1985), and to obtain damages for negligence in preventing civil rights violations (42 U.S.C. § 1986). Furthermore, the Congress enacted the Civil Rights Act of 1875, which prohibited racial discrimination in inns, public conveyances, and places of public amusement, for which criminal penalties were applied for violations.

Even before the enactment of the U.S. Constitution and the Bill of Rights, race was linked to many injustices in criminal law enforcement in America. One of the more well-known early criminal cases involving slaves was the “Great Negro Plot” of 1741 (DiCanio, 1994). A number of African Americans were convicted of theft and conspiring to commit arson and murder. On the basis of what would now be regarded as inadmissible and hearsay evidence, 70 African Americans were banished from the American colonies to Africa, 16 were hanged, and 13 were burned at the stake. A small number of whites were also punished.

This was not the last time that such evidence would be used to convict racial minorities.

Despite the enactment of the Bill of Rights, racial minorities were continuously denied the same rights accorded to whites. For example, slaves were frequently denied the right to testify in court. The tension between the North and South concerning slavery continued to fester and was only temporarily mollified by the Missouri Compromise of 1820, an act intended to regulate the spread of slavery in the western territories.

Perhaps paradoxically, American history contains several instances in which justice was done, albeit for unusual reasons. One such example involved the schooner *Amistad*. A slave, Joseph Cinque, and 49 others, were purchased in Havana, Cuba, and placed on the *Amistad* for delivery to a Cuban plantation. Cinque and other slaves revolted, killing the captain and members of the crew. They eventually arrived in New York City, where they were charged with murder and piracy in 1839. Although eventually acquitted, the acquittal was granted under property law instead of criminal law. The decision was based on the grounds that Cinque and his codefendants were not legally “property” and had been illegally enslaved in Africa. Thus, Cinque and the other slaves had both a valid defense to the criminal charges as well as the right to free themselves (Christianson, 1994a; *U.S. v. The Schooner Amistad*, 1841).

Despite rare decisions like that of the case of Joseph Cinque, the concept of racial inferiority remained pervasive. In the infamous *Dred Scott* decision of 1856, the U.S. Supreme Court reaffirmed the idea that African Americans were inferior as a race (*Scott v. Sanford*, 1857). Scott, an African American slave, had been taken by his owner from a slave state to a free state and brought suit in Missouri to gain his freedom. Although Scott won at trial, the Missouri Supreme Court and the U.S. Supreme Court both held that Scott was property and thus was still a slave (Christianson, 1994b; Hall, 2005). This decision reinforced the position in the United States that actions taken against slaves, which would otherwise be criminal if committed against whites, were not criminal acts.

No discussion of the issue of race and crime would be complete without mentioning John Brown. In 1859, Brown, an ardent abolitionist, attempted to arm and start a revolt among southern slaves. He and his followers seized the federal arsenal at Harpers Ferry, Virginia. After a brief siege, Brown and his followers were captured. Brown was tried in Virginia for charges of insurrection and murder. He was found guilty and hanged (Christianson, 1994c). This case illustrates how, throughout American history, race permeates not just the criminal trials of racial minorities but the trials of whites trying to defend racial minorities.

Civil War Era

Within a few years of the John Brown revolt, the Civil War started. After the defeat of the Confederacy, the Thirteenth, Fourteenth, and Fifteenth Amendments to the

U.S. Constitution were enacted. Reconstruction began in the South, ostensibly as a means to protect the former slaves. Many gains were made for the former slaves. However, Reconstruction, which was essentially administered by the military during the early years after the Civil War, caused a great deal of resentment among southern whites. As a result, lynching and other racially motivated crimes were commonplace (Foner, 1988).

In 1873, in Louisiana, a number of African Americans were lynched concerning voting in a state election. The State of Louisiana, for unknown reasons, failed to prosecute the murder suspects. The U.S. Attorney, seeking to enforce the Civil Rights Act of 1870, indicted more than 100 people for various crimes, including conspiracy. Eight of the suspects went to trial, three of whom were found guilty. They appealed to the U.S. Supreme Court, which reversed the convictions, finding that the indictments were technically insufficient, although some authorities are of the opinion that the reversal was based more on the posture that the criminal charges were more properly brought in state court (*United States v. Cruikshank*, 1875; Hall, 2005).

This setback notwithstanding, a number of criminal cases were brought against private individuals for discrimination. Several of these cases came to the U.S. Supreme Court in 1882. In a combined decision, known as the “Civil Rights Cases,” the Supreme Court struck down part of the Civil Rights Act of 1875, finding that Congress did not have the authority to enact such criminal laws (The Civil Rights Cases, 1883; Hall, 2005). These decisions, *United States v. Cruikshank* (1875) and the Civil Rights Cases (1883), effectively squelched the hope for equal rights for racial minorities, in both civil and criminal actions, in America for almost a century.

After the Civil War: Jim Crow Laws

In the wake of the *Cruikshank* and the Civil Rights Cases, a long interregnum in the South began. So-called Jim Crow laws were enacted all across the South and in the North (Klarman, 2004). Jim Crow laws were statutes enacted to enforce segregation between the white and minority populations. These laws covered almost every aspect of life, including public facilities, restaurants, public transportation, health care, education, employment, and social relationships. Violation of Jim Crow laws frequently resulted in criminal prosecution.

Enforcement of Jim Crow laws came to a head in 1896 with the one of the most infamous Supreme Court decisions: *Plessy v. Ferguson* (1896). Plessy, an African American, had purchased a ticket on a train within the State of Louisiana. He entered a car reserved for whites. Plessy was arrested, taken to jail, prosecuted, and found guilty. Plessy appealed to the U.S. Supreme Court, which, in essence, placed its seal of approval on de facto racial discrimination, by approving the doctrine of “separate but equal” and affirming Plessy’s conviction. The

Supreme Court ignored the fact that accommodations for African Americans were almost never equal and that it was impossible for African Americans to enforce any equality of treatment. Justice John Marshall Harlan, quite presciently, dissenting in the *Plessy* decision, noted that *Plessy* would become as pernicious as the *Dred Scott* decision (Hall, 2005).

Through the early 1900s, racial minorities rarely received due process in criminal trials. Despite the problems, Congress made attempts to enforce civil rights through legislation. For example, it was a crime for government officials to engage in a conspiracy to violate civil rights or to deprive a person of his or her civil rights under the color of law (18 U.S.C. §§ 241, 242, 35 Stat. 1092, 1909). Well intended as they may have been, these statutes were rarely enforced. This situation was aggravated by the rapid postwar increase in membership and influence of the virulently racist Ku Klux Klan (McLean, 1995). Despite these problems, there was still the occasional victory, but usually at great cost.

A noted example occurred during 1919 as a result of race riots in Elaine, Arkansas. A number of sharecropping African Americans held meetings in at the Hoop Spur Church to organize protection from extortive practices of white landowners. In response, the white landowners attacked the sharecroppers. During the clashes, between 100 and 200 African Americans and 5 whites died. A number of African American men were arrested and charged with murder. A "Committee of Seven" whites was appointed to investigate the matter. A lynch mob marched on the jail. The National Guard was summoned in to protect the African Americans. Although the defendants were shielded from the anger of the lynch mob, the subsequent trial was hardly fairer. Witnesses were tortured to compel testimony against the accused. An attorney was appointed for them, but he did not meet with the men before trial. He did not challenge any juror, nor did he ask for separate trials. Moreover, he called no witnesses for the defense, even though they were available. In a 45-minute trial, with the jury deliberating less than 5 minutes, 6 African Americans were found guilty and sentenced to death. Appeals through the Arkansas courts were unsuccessful. Suit for a writ of habeas corpus brought in the federal district court in Arkansas was likewise unsuccessful. Not until the U.S. Supreme Court decided the matter in 1923 was a writ of habeas corpus granted for the wrongful conviction (*Moore v. Dempsey*, 1923; Hall, 2005; Ryan, 1994a). The *Moore v. Dempsey* decision foreshadowed changes to come concerning race and the criminal justice system. It was not enough, however, to prevent one of the gravest racially tainted miscarriages of American justice: the Scottsboro Boys cases.

In Scottsboro, Alabama, in 1931, nine African American youth were accused of rape by two white women. The mood of the local community was ugly, and the National Guard had to be called to prevent the defendants from being lynched. At trial, the judge, after stating that he would

appoint any attorney in the country to represent the defendants, appointed an attorney who was a renowned alcoholic. Despite the lack of inculpatory medical evidence, the Scottsboro Boys were all convicted and sentenced to death save for one, who was granted a new trial. The Alabama courts denied the appeals. The U.S. Supreme Court reversed the convictions for a violation of due process concerning the appointment of the defense attorney (Hall, 2005; Ryan, 1994b).

A second trial in the Alabama courts was scheduled. One of the Scottsboro Boys was again convicted. He was convicted in spite of the following facts: One of the alleged victims recanted, the other victim had been found to have been convicted several times of adultery and fornication, two of the boys had physical limitations preventing them from raping the alleged victims, and the medical evidence again showed that the alleged victims had not been raped. The trial judge set aside the jury's judgment and recused himself under pressure from the attorney general and the chief justice (Hall, 2005; Ryan, 1994b).

A third trial for the Scottsboro Boys in the Alabama courts was held in 1936. Convictions were again obtained. An appeal to the U.S. Supreme Court resulted in a reversal because African Americans had been excluded from jury duty (Hall, 2005; Ryan, 1994b). Even so, a fourth trial was held in Alabama in 1937. Four of the Scottsboro Boys were found guilty of rape. One was found guilty of stabbing a deputy during a jail transfer, and the charges against the remaining four were dropped when a new prosecutor was placed in office. The Alabama governor, cognizant of public opinion, refused to grant a clemency petition after he agreed that "all were guilty or all should be freed" (Hall, 2005; Ryan, 1994b). The *Scottsboro Boys* case has been considered to be perhaps the ultimate example of racial discrimination and the denial of due process in the American criminal justice system.

During World War II, race became an issue in what is probably one of the most shameful events in American history. More than 100,000 Japanese Americans on the West Coast were rounded up and herded into the American version of concentration camps based solely on their race, on the assumption that they might possibly be spies. Even though American officials admitted that there had not been a single case of espionage involving Japanese Americans, the internments continued. Indeed, Japanese Americans volunteered for combat duty in Europe against the Nazis and, in the 442nd Nisei Regiment, amassed numerous battle honors, but still innocent Japanese Americans were criminally prosecuted for failing to report for internment (Irons, 1983; *Korematsu v. United States*, 1944). Indeed, in the *Korematsu* decision, a dissenting justice, Frank Murphy, accused the nation of falling into the ugly abyss of racism and compared the United States to Nazi Germany. Only later in the century, when Fred Korematsu brought a civil suit, were the Japanese Americans finally vindicated (*Korematsu v. United States*, 1984).

Although not a criminal case, *Brown v. Board of Education* (1954) highlights the status of racial minorities in America up to the 1950s. Linda Brown, a young African American girl, was denied enrollment in a white school in Topeka, Kansas, and was required to travel a long distance to attend a black school. Brown brought suit. The lower courts, relying on the decision in *Plessy v. Ferguson* (1896), denied the suit. Brown appealed to the U.S. Supreme Court. In 1954, the Supreme Court overruled *Plessy* and rejected the doctrine of separate but equal, deciding that segregation was inherently unequal (*Brown v. Board of Education*, 1954; Hall, 2005).

The 1960s to the Present

The 1960s were a significant period of upheaval and change in society and for minorities in the American justice system. With broad changes such as the Civil Rights Act of 1964 (Pub. Law 88–352, 78 Stat. 241) and the National Voting Rights Act of 1965 (42 U.S.C. § 1973–1973aa-6), the legal landscape slowly adapted to the realities of past injustices. A number of criminal cases decided by the U.S. Supreme Court under Chief Justice Earl Warren added to this change (Schwartz, 1996). During 1961, the Supreme Court decided the case of *Mapp v. Ohio* (1961). By its decision in *Mapp*, the U.S. Supreme Court overruled *Wolf v. Colorado* and held that the exclusionary rule—that evidence seized in violation of the Fourth Amendment was held inadmissible in both state and federal criminal proceedings—was directly applicable to the states. However, the *Mapp* decision is also important in regard to the issue of race and the criminal justice system. The defendant, Dollree Mapp, was an African American woman whose house was illegally searched without a warrant. The *Mapp* decision was the first landmark decision concerning the universal application of a constitutional rule of criminal procedure involving a racial minority (Long, 2006).

The 1960s also saw the decision of the U.S. Supreme Court in *Miranda v. Arizona* (1966). Ernesto Miranda was a Hispanic man arrested for rape and kidnapping. He was not well educated. Despite maintaining his innocence, after police interrogation Miranda signed a confession that led to his conviction. Miranda subsequently appealed, and the U.S. Supreme Court ruled that police had to advise suspects of their rights, to include access to counsel, before interrogation. The *Miranda* decision reinforced the principle that even the lowliest person was entitled to the rights of criminal procedure guaranteed by the Constitution and the Bill of Rights and that minorities should be given equal protection of the law (Hall, 2005).

Capitalizing on these principles, under Chief Justice Warren, the U.S. Supreme Court expressly overruled a number of the Jim Crow laws enacted in the late 19th and early 20th centuries. In *McLaughlin v. Florida* (1964) and *Loving v. Virginia* (1967), the Warren Court struck down laws that criminalized interracial marriage.

Although not directly concerning criminal prosecution, a decision of the Warren Court in 1961 allowed those persons who suffered violations of their civil rights in the context of criminal investigations and prosecutions to seek civil relief under the Civil Rights Act of 1871 and 42 U.S.C. § 1983. In *Monroe v. Pape* (1961), the U.S. Supreme Court allowed civil rights suits against government officials to be brought for damages. This was an extraordinary decision that breathed life into the Civil Rights Act of 1871 and 42 U.S.C. § 1983, which had been rarely used since its enactment almost a century before. Since that decision, suits brought under these laws have limited the powers of the government to enforce criminal law and required the more just and equitable application of the criminal law for minorities under the equal protection and due process clauses of the Fourteenth Amendment.

Many more civil rights laws were passed in the 1960s. Relative to criminal law, one of the most important was probably 18 U.S.C. § 245, which criminalized both private and public discrimination (Pub. Law 90–284, 82 Stat. 73, 1968). This statute was, in essence, another attempt to make such discrimination criminally illegal, as was done with the Civil Rights Acts of 1870 and 1871, which had been undermined by previous Supreme Court decisions.

Despite the myriad legislation and judicial decisions recognizing the inappropriateness of race as a factor for limiting a person's rights, law enforcement agencies continued to use race as a factor. Among the most notorious examples of this is a Federal Bureau of Investigation program known as COINTELPRO. This program, along with others, resulted in the illegal surveillance and harassment of Martin Luther King and the Black Panther Party (Burnham, 1996).

Any review of race and crime in the United States must include a discussion of the death penalty. It is undisputed that in the American criminal justice system, African Americans are executed at a rate much greater than whites. Illustrative of the problem is the case of *Furman v. Georgia* (1972). Mark Furman, a young African American man, was charged with murder subsequent to burglarizing a home and killing the homeowner who had interrupted the burglary.

Furman, both indigent and with psychological problems, received a court-appointed lawyer, who was paid \$150. Upon his conviction, Furman appealed. The U.S. Supreme Court found that the death penalty was disproportionately applied to racial minorities and overturned the conviction. Although the *Furman* decision did not invalidate the death penalty, it restricted its application. Within a few years, the Supreme Court, in its decision in *Gregg v. Georgia* (1976), added additional restrictions on the death penalty and its application to minority groups (*Gregg v. Georgia*, 1976; Hall, 2005).

Obviously, all the problems concerning race and the criminal justice system were not resolved in the 1960s and 1970s. The Supreme Court has repeatedly heard cases alleging racial discrimination. In the 1980s, the U.S.

Supreme Court addressed the issue of exclusion of jurors on the basis of race. Even though each party (i.e., prosecutor and defendant) has the right to exercise a certain number of peremptory challenges to a juror for which a reason does not have to be given, the court ruled that it was unconstitutional to use such challenges against jurors on the basis of race (*Batson v. Kentucky*, 1986).

Race continued to be a troublesome issue for law enforcement in the 1990s. The Rodney King case provides a well-known example. King was arrested in 1991 and during the arrest was beaten by a number of California police officers. The officers were acquitted in state court of criminal charges. However, they were subsequently indicted in federal court for criminal civil rights violations under 18 U.S.C. § 242. Two of the officers were found guilty and sentenced to prison (*Koon v. United States*, 1996). The King incident highlighted what many minorities assert is the continuing unequal treatment afforded to racial minorities in the enforcement of the criminal law.

Furthermore, in the 1990s, criminal law enforcement was taken to task for the unequal enforcement in what is commonly known as the “driving while black” lawsuit (*Maryland State Conference of the NAACP v. Maryland State Police*, 1998). A number of law enforcement agencies engaged in the practice of *racial profiling*, whereby a person is suspected of committing a crime simply on the basis of—or in part because of—his or her race. Lawsuits such as this, combined with public and political pressure, have reduced the incidence of such law enforcement practices, but they still exist.

Even today, during the early part of the 21st century, matters of race continue to plague the criminal justice system. For example, for decades the rate and extent of incarceration of racial minorities in prison have far exceeded the imprisonment rate and extent of whites.

History indisputably shows that race has been and still is a significant factor in the enforcement of the criminal law in the United States. With the Warren Court in the 1960s, significant improvements to the criminal justice system concerning its intersection with race have been made. There has been moderate, if only minimal improvement since that time, with the changing of the political environment and the U.S. Supreme Court to a more conservative perspective. As a matter of law and policy, the issue of race in the criminal justice system has witnessed positive changes, but there remains much to be done to ensure racial equality in the American criminal justice system.

RELIGION AND CRIME

KENT R. KERLEY

University of Alabama at Birmingham

An impressive research literature that identifies linkages between religion and a wide range of attitudes, behaviors, and life events has emerged. This research suggests that religiosity—a cognitive and behavioral commitment to organized religion—is associated with factors such as interpersonal friendliness; psychological and physical well-being; comfort for those who face difficult life situations, such as family problems, divorce, and unemployment; marital happiness; participation in politics and political movements; and volunteering in community organizations. A recurrent theme in this literature is that religion may operate as a social force for reducing negative behaviors and for increasing positive behaviors.

The relationship between religion and crime, however, is not as straightforward. Research on this topic since the 1960s has yielded widely varying results. Whereas many studies have found that religion is significantly related to a host of crime-related factors, others have found no relationship. This chapter is designed to introduce readers to the extensive literature on religion and crime. It is organized along three dimensions. First, research on the relationship between religion and the commission of criminal and deviant acts is discussed. Second, research on religion in the prison context is reviewed. Third, research on the relationship between religion and crime control attitudes is presented.

Religion and Criminal or Deviant Behaviors

Researchers have long sought to understand the relationship between religion and the commission of criminal or deviant behaviors. French sociologist Émile Durkheim (1897) was one of the first to consider this topic. Durkheim believed that religion operated as a social force such that greater levels of religious commitment should lead to reduced negative behaviors. Before the empirical research on this topic is discussed, the important question to address is how religion may reduce criminal or deviant behaviors. The answer lies in insights drawn from *social capital theory* (Coleman, 1988) and *social control theory* (Hirschi, 1969). Many researchers contend that religious involvement may create social networks and emotional support that will constrain criminal behavior. Religious individuals tend to be bonded to religious institutions that provide informal social control over their behaviors. The behavior of individuals with higher levels of religiosity is thought to be guided by the sanctions derived from religion. According to this logic, religiosity may operate as a shield against negative behaviors such as crime and deviance by creating and reinforcing social networks and social bonds.

Closely related to the avoidance of criminal and deviant behaviors is the promotion of prosocial behaviors. Christopher Ellison (1992) contended that religiosity may

be linked with prosocial behaviors for two key reasons. First, individuals with higher levels of religious commitment are more likely to engage in religious role-taking such that they interact with others according to their perceptions of what a “divine other” would expect. Religious individuals may view life from “the vantage point of the ‘God-role,’ by attempting to understand how a divine other would expect them to behave toward their fellows” (Ellison, 1992, p. 413). Second, religious individuals may internalize religious norms concerning kindness, empathy, and civility. Scriptural stories such as the Good Samaritan and scriptural precepts such as the Golden Rule provide structure and a model for relationships with others.

Review of Empirical Studies

The first major empirical study of religion and crime was conducted by Travis Hirschi and Rodney Stark (1969). They used survey data on youth from California to test the *hellfire hypothesis*, which predicted that religion could deter crime on the individual level through the fear of supernatural sanctions and at the same time encourage prosocial behaviors through the hope and promise of supernatural rewards. The authors investigated whether individuals who attended church were less likely than individuals who do not attend church to engage in a variety of delinquent behaviors. They also investigated whether belief in supernatural sanctions for bad behavior deterred the same delinquent behaviors. Hirschi and Stark found no relationship between religious attendance or belief in supernatural sanctions and self-reported delinquent acts. They concluded that respondents’ decisions to commit crimes were linked with perceptions of pleasure and pain on earth, instead of on perceived heavenly rewards for good behavior or the punishment of hellfire for sinful acts. Since Hirschi and Stark’s landmark study, investigators have produced approximately two studies per year on this topic. The relationship between religion and crime has also been the subject of a meta-analysis (Baier & Wright, 2001) and a systematic review (Johnson, De Li, Larsen, & McCullough, 2000).

In a subsequent study, Stark, Kent, and Doyle (1982) suggested that the findings from Hirschi and Stark’s (1969) study were largely due to the moral makeup of the area in which it was conducted (Richmond, California). In what has become known as the *moral communities hypothesis*, Stark et al. contended that religion is best understood as a structural property of communities rather than as an individual attribute of persons. In other words, religion is most likely to reduce crime and deviance in more religious areas of the United States (e.g., Southeast, Midwest), and is less likely to do so in less religious areas (e.g., Northeast, Pacific Northwest). In terms of church membership and church attendance, Richmond, California, had very low rates of religious commitment relative to the rest of the country. Stark et al. characterized this area as a “secular

community” rather than as a “moral community.” The moral makeup of the community thus helped to explain why religiosity did not reduce crime in the original study (see also Stark, 1996).

Similar to Stark et al. (1982), Higgins and Albrecht (1977) suggested that the absence of a significant relationship between religiosity and delinquency in Hirschi and Stark’s (1969) landmark study stemmed from the use of a sample from a primarily nonreligious Western population. Higgins and Albrecht analyzed a sample drawn from the more religious-oriented South and found that religiosity led to reductions in the amount of self-reported crime and deviance. They also found that, in addition to religiosity, peer expectations and relationship with parents were predictors of crime and deviance. Thus, Higgins and Albrecht concluded that Hirschi and Stark’s research may have yielded accurate results for the western area they studied, but the results of studies conducted in other areas of the country, characterized by strong religious communities, are likely to be the opposite.

Burkett and White (1974) offered a rival explanation to Hirschi and Stark’s (1969) findings. They suggested that the effects of religion on crime will vary depending on the type of crime. Using survey data on high school students in Pennsylvania, they found that religion is most likely to reduce behaviors that have a strong moral or ascetic connotation in religious circles but are not universally looked down on in society (e.g., alcohol and drug use, gambling, premarital sex). The authors reported that higher levels of religious participation led to significant decreases in students’ use of alcohol and marijuana, but it did not influence involvement in property or violent offenses. Burkett and White’s work comprises what is called the *anti-asceticism hypothesis*.

Using data on middle and high school students in three midwestern states, Cochran and Akers (1989) reached a conclusion similar to that of Burkett and White (1974). Cochran and Akers tested several competing theories of the relationship between crime and delinquency and found that the anti-asceticism hypothesis received the most support; specifically, the more religious students in the sample reported significantly lower levels of alcohol and marijuana use than less religious students and nonreligious students, but there was no significant effect of religion on other types of crimes.

Lee Ellis (1987) suggested that the relationship between religion and crime is spurious; that is, the relationship is contingent on another factor, which in this case is the arousal level of each individual. According to Ellis’s *arousal theory*, criminal behavior is related to innate variations in each individual’s demand for neurological stimulation. Ellis contended that criminals are naturally prone to boredom and that criminal actions are a means of finding arousal through risk-seeking behavior. If individuals have suboptimal arousal levels (a tendency to be bored), they

will seek stimulation to meet their psychological and physiological needs. This need for stimulation is greater than for individuals with normal levels of arousal. This is not to say that all stimulation sought by suboptimal individuals will be criminal but that the risk-seeking behaviors may, in some cases, be criminal.

In terms of religiosity, Ellis (1987) predicted that individuals who have suboptimal arousal levels will have low levels of church attendance, because religious services often are routine and solemn events. In Ellis's test of his theory, he measured religion on the basis of church membership, church attendance, belief in God, denominational measures, belief in immortality, and other beliefs. He then measured arousal in two ways: (1) neurological and (2) extraneurological. The neurological measure included basic brain wave readings from an EEG. Extraneurological measures were divided into two subcategories: (1) physiological measures and (2) self-reported measures. Physiological measures involved skin conductivity and other arousal indicators, such as heart and pulse rates, startle reflexes, and adrenaline secretions. The self-reported measures consisted of responses about the exciting and boring activities in which the participants took part.

On the basis of this research, Ellis (1987) reached three main conclusions: (1) Among church members, those who attended church more often exhibited lower crime rates than those whose attendance was infrequent; (2) those who believed in an afterlife where their sins would be punished had lower crime rates than those who lacked the same belief, and (3) Jewish crime rates were lower than for Christians, and Protestants had lower crime rates than Catholics. He concluded that religious participation was associated with lower levels of criminal conduct; however, he found that the observed relationship between religion and crime was no longer strong once the level of arousal was accounted for. Thus, Ellis concluded that arousal level was the best predictor of both religiosity and criminal behavior.

Cochran and colleagues (Cochran, Wood, & Arneklev, 1994) used data on high school students in Oklahoma to investigate whether religion could reduce the incidence of several different types of crimes. Along with measures of religiosity, the authors included measures based on arousal and social control theories. Similar to Ellis (1987), the authors found that the religion–crime relationship was spurious; more specifically, the relationship between religion and crime disappeared once the arousal levels and social controls of the individuals were accounted for.

Benda and Corwyn (1997) analyzed data on students in three Arkansas high schools to determine whether religion was related to several different types of delinquent and criminal behaviors. They found that greater levels of religiosity (in particular, church attendance) reduced the likelihood of status offenses (e.g., skipping school, fake excuses for missing school, running away) but did not reduce the likelihood of several crimes against persons or

property. When measures of social control were accounted for, however, the relationship between religiosity and status offenses disappeared, and there was still no effect of religiosity on crime.

Byron Johnson and his colleagues (Johnson, Jang, Larson, & De Li, 2001) analyzed data from the National Youth Survey and came to a very different conclusion about the relationship between religiosity and delinquency. They attempted to explain involvement in 35 different types of delinquent behavior on the basis of religiosity, social controls, and social learning, and found that religiosity directly reduced delinquent behavior, even after controlling for youth's social bonds to society and the extent of their delinquent associations.

Welch, Tittle, and Grasmick (2006) examined the relationships among religiosity, self-control, and crime. They analyzed survey data on adults in Oklahoma to determine the key predictors of five different types of crimes. The authors found that religiosity and self-control operate on significant, independent tracks for deterring crime. In other words, higher levels of religious commitment directly reduced the likelihood of criminal activities even after accounting for individuals' level of self-control.

Finally, two sets of scholars compiled and reviewed a large number of empirical studies of religion and crime to determine the overall strength and nature of the relationship. Johnson and associates (Johnson, De Li, et al., 2000) reviewed 40 studies of the relationship between religion and delinquency conducted between January 1985 and December 1997. They used a method called *systematic review*, which involves a search of all peer-reviewed journals in the social and behavioral sciences. Of the 40 studies of religiosity and crime/delinquency they identified, 30 indicated that religion had a beneficial effect (i.e., led to reductions in) on many types of criminal and deviant behaviors. The 10 remaining studies showed either no effect (5 studies), mixed effects (3 studies), positive effects (1 study), or effects not specified (1 study). Thus, Johnson et al. concluded that the research literature consistently has shown that religion leads directly or indirectly to reductions in criminal and deviant behavior. Baier and Wright (2001) reviewed 60 studies of religion and crime that were conducted between 1969 and 1998. They concluded that, overall, religion had a “moderate” effect on reductions in criminal and deviant behaviors.

Religion and Prison

The relationship between religion and crime has also received attention from scholars who have studied religion in the prison context. Religion has been a tool for correctional treatment since the inception of the penal system in the United States. In fact, the first penitentiaries were developed by Quakers for offenders to study the Bible to facilitate their rehabilitation. Currently, most states employ

full-time chaplains and allow members of local religious congregations to promote faith to the incarcerated. Before studies of religiosity and faith-based programs in prison are reviewed, it is important to learn more about prison chaplains and local religious congregants.

Prison Chaplains and Local Religious Congregants

Much of the literature on prison chaplains has been written by chaplains themselves. The most prevalent topic in the literature is the transformation of their position in the last century from guiding inmates to spiritual conversion to serving as counselors, organizers, and liaisons for inmates. One particular concern for chaplains is balancing the provision of religious programs with active proselytization. The once-accepted practice of using inmates as a “captive audience” for chaplains has now been dismissed. It is unethical, and in some cases illegal, for chaplains to force inmates to attend a religious program. In addition to not forcing their beliefs on inmates, prison chaplains must be respectful of whatever religious beliefs are present in the prison. The majority of inmates and chaplains identify with some form of Christianity, but a growing minority adhere to other religions, including Islam and Judaism. Chaplains must ensure that inmates have the materials and personnel necessary to fulfill the religious rites of the faith tradition to which they adhere.

Sundt and Cullen (1998) sought to determine the types of tasks prison chaplains spent most of their time doing in order to categorize those tasks as either spiritual or secular. They also attempted to determine whether what chaplains *perceive* they should be doing is what they actually *are* doing. The authors mailed questionnaires to a sample of 500 chaplains. They hypothesized that chaplains would see spiritual duties as their primary responsibility but that they would report being responsible for more secular duties. The authors found that chaplains consider the secular activity of counseling inmates to be their highest priority and the area on which they spend the most time. The study showed that, with the exception of the time spent coordinating volunteers, chaplains mostly spent their time on the tasks they perceived to be most important. Most chaplains perceived their role to be primarily supportive of inmates, but custodial activities were a substantial part of their job as well. Sundt and Cullen concluded that it does appear that chaplains have secular activities, such as counseling, as their primary responsibility; however, this did not appear to produce greater role ambiguity among the chaplains than for most people working in corrections.

In a follow-up study conducted on the basis of data on chaplains in New York, Sundt, Dammer, and Cullen (2002) measured chaplains’ support for treatment, the amount of counseling done by chaplains, and the content of the counseling sessions. Most chaplains favored treatment and rehabilitation along with punishment and did not see the

rehabilitation model as a failure. They found that chaplains used a variety of counseling methods during their sessions; however, most reported using a spiritual orientation in these sessions. As these studies demonstrate, counseling has become one of the most important aspects of modern chaplaincy. However, in addition to counseling inmates, chaplains are expected to be a liaison between inmates and the rest of the correctional staff and, in some cases, even an advocate for inmates.

In a third study, Sundt and Cullen (2002) surveyed chaplains to determine their perspective on the purpose of imprisonment. They hypothesized that those who are in the field of service, such as chaplains, would be more supportive of rehabilitation efforts and less likely to be punitive. They found that although almost half of the chaplains thought that the primary purpose of incarceration should be incapacitation, when they had to choose between rehabilitation and punishment, they chose rehabilitation. Not surprisingly, chaplains thought that religion was the best method for reforming inmates. The authors concluded that chaplains support rehabilitation and consider their work to be such. Chaplains who felt called to work in chaplaincy and those who viewed God as forgiving were more likely to have a rehabilitative view.

As the responsibilities of prison chaplains change and prison populations increase, local religious congregants are a more vital part of faith-based prison programs. With an increase in secular responsibilities and shortage in money per inmate, chaplains increasingly rely on local religious congregants to help with the workload. Local religious congregants can be helpful when inmates have spiritual requests for which chaplains are not trained or equipped to respond. Tewksbury and Dabney (2004) found that nearly 60% of prison volunteers reported contributing financial or material goods to their work. That is substantial support in an overcrowded prison system in which budgets are limited for rehabilitation programs. The downside of looking to the community for help is that, as a result of budget cuts, chaplains themselves are being replaced by local religious congregants in order to cut costs. According to chaplains, the main disadvantage of this trend is that local religious congregants do not have the training that is required of chaplains. Chaplains are necessary to train the congregants visiting the prison so that they are aware of and adhere to the rules of the facility. Also, local religious congregants cannot be expected to meet all of the demands required of a chaplain, including counseling and advocacy.

Tewksbury and colleagues conducted two studies of prison volunteers. In the first study, Tewksbury and Dabney (2004) surveyed volunteers at a southern prison who were attending a mandatory training session. The point of the survey was to determine who was volunteering, why, and how he or she benefited. The most frequently reported motivation for coming to the prison was to share religious beliefs. Other reasons for volunteering were to help others, because they were asked to do so, or because they had a

relative in prison. Overall, the ratings the volunteers gave for their experience and satisfaction were positive. The questions regarding satisfaction all averaged over 7 on a scale of 1 to 10, with 10 representing complete agreement. Nearly half of the volunteers listed seeing a change in the inmates as the most rewarding part of their experience. Tewksbury and Dabney concluded that the main population of volunteers came from the religious community. Those volunteers showed high levels of satisfaction and showed that they are willing to make sacrifices in order to volunteer.

In a more recent study, Tewksbury and Collins (2005) surveyed a different group of local religious congregants doing faith-based prison work. They asked these congregants about the same motivations and their perceived rewards from the work in order to help recruit future local religious congregants. In this instance, the authors used anonymous surveys, which were distributed to local congregants who volunteered in three Kentucky prisons. The vast majority identified with some form of Christianity, and most had served more than 1 but less than 10 years as a volunteer. There were a multitude of tasks that were reportedly done by the local religious congregants. The most commonly reported tasks were teaching, preaching, counseling, and studying religious texts. Nearly all prison volunteers reported intrinsic rewards, such as feeling that they were serving God and had a true sense of purpose.

Review of Empirical Studies

Researchers who study religion in the prison context have focused on two issues: (1) whether inmates' level of religiosity affects prison behavior and (2) whether religiosity reduces the likelihood of arrest after release (i.e., recidivism). Several of the major studies of religion in prison context have been conducted by Johnson and his colleagues. Using a sample of inmates released from a Florida prison between 1978 and 1982, Johnson (1987) found that inmate religiosity, chaplains' assessment of inmate religiosity, and inmate religious service attendance did not affect the number of prison infractions committed or the amount of time inmates spent in disciplinary confinement.

Johnson, Larson, and Pitts (1997) conducted an evaluation of a faith-based program sponsored by Prison Fellowship Ministries (PFM). A sample of prisoners in four New York state prisons was chosen because the PFM staff in that prison had kept thorough records. Among the 40,000 inmates in the four prisons, 201 male prisoners were chosen on the basis of their similarities to the control group. Inmates were categorized on the basis of how often they participated in three different kinds of religious programs and the length of time they were involved in an activity. Inmates who participated in 10 or more activities per year were considered highly active, those participating in 1 to 9 programs were considered medium active, and those who did not attend were classified as

inactive. Johnson et al. evaluated the inmates' incident records while incarcerated as well as their arrest records up to 1 year after release. They hypothesized that the number of infractions while incarcerated, including serious infractions, would be inversely proportional to level of participation in PFM programs and that inmates who were most active would be less likely to be rearrested than those who had less participation.

Johnson et al. (1997) found that participation in PFM activities was not related to the prison infractions; in fact, inmates who were most active in PFM activities were most likely to have a record of serious infractions. The authors were unable to determine which activity was first (the PFM activity or the infraction) but suggested that the inmates might have committed the infractions and then turned to religion to make amends. Inmates involved in PFM activities did not have a significantly reduced likelihood of recidivism compared with the control group. However, Johnson et al. found that inmates who were most heavily involved in PFM activities were much less likely to have been arrested 1 year after their release than individuals in the control group.

In 2004, Johnson conducted a follow-up study with several modifications. In particular, he changed the definition of *active participation* and increased the amount of time evaluated after the inmates were released. By lowering the number of activities in which inmates must participate to be considered having high participation from 10 or greater to 5 or greater, and increasing the time after release from 1 year to 8 years, he was able to determine more thoroughly the effect of involvement in PFM activities. Johnson found little difference between the median arrest times and reincarceration rates between PFM and non-PFM inmates. The survival rate, or the rate at which inmates were arrested after release, was slightly lower for the PFM group at 8 years, but the only significant differences appeared when highly active inmates were compared with low-activity inmates. Program attendance was insignificant when predicting recidivism, and participation in PFM programs was insignificant as a predictor compared with virtually all other variables through the 8-year mark. Johnson concluded that there was little difference in recidivism rates between inmates at different levels of participation after 8 years.

Todd Clear and his colleagues (Clear, Hardyman, Stout, Lucken, & Dammer, 2000) studied the potential benefits of any type of faith-based prison activity. They noted that although religion might be popular as a way to reduce recidivism, historically, any method for reducing recidivism will fall out of favor if it does not produce significant results. They sought to determine what benefits inmates could receive from religious activities in prisons. Clear et al. used both survey data and an ethnography of inmates involved in Christian and Muslim religious activities over the course of 10 months. They looked at the intrinsic values of being outwardly religious for prisoners,

which they defined as the part that religion plays in helping them deal with the bad feelings they experienced because of their incarceration. They proposed that inmates who are active in religious activities would report, or have reported about them, mental or behavioral differences compared with those who were not active in the religious activities. This would demonstrate that religion can have intrinsic value in prison outside of any value it may have in reducing recidivism.

The results supported Clear et al.'s (2000) expectations that inmates who were active in religious activities differed from those who were not active in regard to emotional health, prosocial behaviors, and the benefits they received. They found that faith allowed inmates to receive forgiveness and to make restitution for their offenses. Also, it gave them hope that they could turn their lives around when they were released. The most religiously active inmates reported that religion allowed them a mental escape from the realities of prison life and helped to prevent involvement in activities that could cause them trouble.

Clear et al. (2000) also looked at the extrinsic values of religious participation in terms of how faith affects inmates' relationships with others. Involvement in religious activities benefited inmates by providing them with a safe context in which to forge positive relationships in prison. These friends ensured a measure of safety. Especially for inmates practicing Islam, being part of a group provided them with a certain amount of protection, because their group was bound to protect them. Also, the physical act of going to religious activities or acting out religious rituals kept an inmate out of trouble or in safe places, such as the chapel. Being active in religious programs also allowed inmates to create relationships with individuals visiting from outside prison. This contact with those in the free world gave inmates a feeling that they had not been forgotten by society. The authors concluded that religious activities in prison can provide inmates with a way of coping with the shock that prison life can present (see also Clear & Sumter, 2002).

Kent Kerley and his colleagues (Kerley, Matthews, & Blanchard, 2005) studied the effect of religiosity on negative prison behaviors, specifically to determine whether it reduced frequent arguments and fights. A random sample of inmates at a large southeastern prison facility completed a survey relating to personal background, religious background, involvement in religious activities, and fighting or arguing with other inmates. The key outcome measures were arguing with other inmates and fighting with other inmates one or more times per month. The authors found that there is a correlation between religiosity and the amount of arguments in which inmates engage. Inmates who reported belief in a higher power and regularly attended prison religious services had a significantly lower likelihood of arguing once or more per month than those who did not. Religiosity reduced inmate fighting not directly but indirectly, by reducing the frequency of arguments.

In a follow-up study, Kerley, Allison, and Graham (2006) found that religiosity did not lead to a significant reduction in the experience of a range of negative emotions. They concluded that prison life is emotionally debilitating to the point that religion does not seem to reduce the experience of negative emotions but does appear to structure interpersonal relationships in prison by reducing negative interactions that could escalate to serious interpersonal conflicts.

Camp, Klein-Saffran, Kwon, Daggett, and Joseph (2006) found that inmates who participate in religious programs are seeking their way in a religious sense. They found that inmates who had a religious identity prior to incarceration were less likely to volunteer for religious programs offered in prison. They argue that religious programs are effective in reducing prison deviance and recidivism only for those inmates who are highly involved and not for inmates who have only a moderate or small amount of involvement.

Religion and Crime Control Attitudes

The third area in which investigators have studied the relationship between religion and crime is in regard to how religious ideology influences attitudes toward crime control. Overall, this research has demonstrated consistently that conservative Protestants (also referred to in the literature as *evangelicals* or *fundamentalists*) are more likely to support punitive crime control measures such as stricter sentences, three-strikes laws, capital punishment, and boot camps. Moreover, investigators have studied the relationship between religion and the perception of wrongfulness of crimes. Using survey data from Oklahoma, Curry (1996) examined the relationship between conservative Protestant beliefs and the perceived wrongfulness of crimes. He concluded that conservative Protestantism was positively associated with higher ratings of perceived wrongfulness of crimes when compared with other religious traditions and nonreligious orientations. Thus, both in terms of attitudes toward criminal sanctions and the seriousness of crime, evangelical Protestants are thought to hold more punitive and stringent attitudes compared with their nonreligious and mainline counterparts.

The important theoretical question is why conservative Protestants are more likely to support punitive treatment of criminal offenders than their nonreligious and mainline religious counterparts. According to John Bartkowski (2001, 2004), conservative Protestants typically privilege the logic of *justice* over the logic of *mercy*. The logic of justice places a premium on the judgment and condemnation of wrongdoing. It is focused on morality and emphasizes the punitive consequences of antisocial and criminal behaviors. By contrast, the logic of mercy stresses the importance of forgiveness of wrongdoers and highlights opportunities for redemption. In the Christian context, the logic of justice distinguishes the sheep (the saved) from the

goats (the damned), whereas the logic of mercy stresses the equality of “God’s children,” all of whom are in need of divine redemption. In addition, conservative Protestants are more inclined to embrace an individualistic worldview that downplays the role of structural explanations for human behavior. Closely linked to this commitment to individualism, religious conservatives believe that moral accountability, which is facing the consequences for one’s actions, is of key importance.

The conservative Protestant tendency to prioritize justice over mercy does not mean that religious believers are incapable of exhibiting compassion. In fact, there is growing evidence that although the logic of justice predominates in conservative Protestant congregations, it is often intertwined with the logic of mercy. Recent survey research reveals that religious adherents who embrace images of God as loving and forgiving are less likely to support punitive reactions to criminal offending. Applegate, Cullen, Fisher, and Vander Ven (2005) considered the effects of religious forgiveness and the influence of traditional conservative religious views on punitiveness for offenders. Using survey data from Ohio, they found that a literal interpretation of the Bible and a punitive image of God were significantly related to favoring punishment and opposing rehabilitation programs for offenders. Conversely, they found that persons with stronger values of religious forgiveness were less likely to support capital punishment and less likely to support punitive approaches to offenders. Furthermore, stronger attachments to religious values of forgiveness were positively associated with favoring rehabilitation and treatment.

Unnever, Cullen, and Applegate (2005) investigated what they referred to as the “neglected variables” (compassion, forgiveness, and an image of a gracious God) from prior studies of religion and punitiveness. Using data from the 1998 General Social Survey, they found that all three of these measures of religious orientation were associated with being less punitive. The authors reported that individuals who truly can “turn the other cheek” and are compassionate toward others are less supportive of “get tough on crime” policies. In a follow-up study, Unnever and Cullen (2006) investigated whether Christian fundamentalists were more likely than nonfundamentalists to support capital punishment. Their results indicated that fundamentalists hold more religiously conservative beliefs, are more likely to express forgiveness and compassion, and are not more likely to support the death penalty than nonfundamentalists.

In a subsequent study analyzing data from the 2004 General Social Survey, Unnever, Cullen, and Bartkowski (2006) hypothesized that individuals reporting a personal relationship with a loving God would reject the worldview that punitiveness is an appropriate response to human failings. They argued that instead, forgiveness and unconditional love and mercy are extended from God to all who have failed or sinned. Their findings indicated

that individuals with a close relationship with a loving God were significantly less likely to support capital punishment. The authors theorized that people with a close relationship with God are less likely to support the death penalty because it contradicts the power and purpose of God, denies offenders the opportunity for redemption, and is in opposition to the sentiment that only God can give and take away life (Unnever et al., 2006).

Thus, the current literature suggests that the religious convictions and practices of conservative Protestants are complex, not simple reflections of a punitive worldview. Local parishioners who focus on individualism and moral accountability prioritize the logic of justice in forming their crime control attitudes (e.g., judgment of wrongdoers, punitive consequences for transgression). Parishioners who focus on compassion and redemption prioritize the logic of mercy in forming their crime control attitudes (e.g., forgiveness of wrongdoers, reconciliation following repentance).

Limitations of Studies

Many scholars have noted several important limitations of the research literature on religion, crime, and faith-based prison programs. First, scholars have questioned the quality and quantity of the measures of religiosity in some previous studies. Johnson, De Li, et al. (2000) found in their systematic review that only about half of the 40 studies they reviewed included three or more measures of religiosity. They also found that only 65% of the studies measured religious attendance, and only 35% measured time spent in prayer. Second, many studies were based on samples of individuals who had volunteered for faith-based interventions, as opposed to participants who had been randomly assigned to a religious or nonreligious group. This allows for the possibility of self-selection bias, because the effects of a religious program may be due not to the program itself but to whatever caused individuals to get involved in religion in the first place. Third, the large majority of studies have used all-male or predominantly male populations in the U.S. general population or in U.S. prisons. Additional research needs to be conducted with females and in other countries. Fourth, the overwhelming majority of studies have used cross-sectional data gathered at one point in time instead of longitudinal data gathered at multiple points in time. For example, only 5 of the 40 studies reviewed by Johnson, De Li, et al. (2000) used longitudinal data. Thus, more longitudinal studies are needed to determine the long-term impact of religion on crime, deviant behavior, prison behavior, recidivism, and crime control attitudes.

Conclusion

An impressive body of research has identified a significant relationship between religion and a wide range of

attitudes, behaviors, and life events. Studies of the relationship between religion and crime, however, have not shown the same significant and uniform effects. This chapter has provided a review of the literature on religion and crime from three distinctive topic areas: (1) the effects of religion on the commission of criminal and deviant acts, (2) the effects of religion on prison misconduct and recidivism, and (3) the effects of religion on attitudes toward crime control. Studies in all three areas suggest a nuanced and inconsistent relationship between religion and crime. It is fair to say that religion, to varying degrees, is related to several crime-related factors. Additional research is needed to explore further the relationship and to understand the nuances. So long as religion continues to be a recognizable and prominent social institution, researchers will continue to assess the extent to which it influences crime and related factors.

SOCIAL CLASS AND CRIME

MICHAEL T. COSTELLOE AND RAYMOND J. MICHALOWSKI

Northern Arizona University

The relationship between social class and crime has been a long-standing source of debate in criminology. Specifically, there is considerable disagreement as to whether crime is largely a lower-class phenomenon or is more broadly and equally distributed. The significance of this debate, and thus its longevity, stems from the fact that most established criminological theories are predicated on the belief that there is something about a lower-class lifestyle that is inherently criminogenic. In fact, during the early and middle decades of the 20th century, most new criminological theories began with the assumption that crime was primarily a lower-class phenomenon (see, e.g., Cloward & Ohlin, 1960; Cohen, 1955; Miller, 1958, Shaw & McKay, 1942).

More recently, the assumption of lower-class exceptionalism has been challenged by empirical research that has attempted to determine the class–crime relationship instead of accepting it as the starting point for criminological inquiry. Unfortunately, because of disparate findings and inconclusive results, criminologists have yet to establish a conclusive answer regarding the class–crime relationship, a relationship that is further complicated when crimes of the powerful, which normally are excluded from criminological analyses of class and crime, are entered into the equation.

This chapter examines the possibility that differing conclusions about class and crime by researchers supposedly analyzing the same phenomenon may be rooted in methodological differences. It also considers the possibility that if the long-assumed causal relationship between lower social classes and criminality is incorrect, not only are many theories of nature and origins of crime based on an erroneous supposition, but the criminal justice policies based on these theories are also formulated on a fundamental misperception. Most crime control policies disproportionately target individuals from the lower classes while ignoring the harms caused by people in the upper classes. If crime and other harmful activities are, in fact, more widely distributed across social classes, these policies, then, may be ineffectual at best and, at worst, counterproductive or even harmful when it comes to combating crime and reducing the harm that it causes.

There are several notable aspects of the relationship between social class and crime: (a) how social class shapes the definition of crime, (b) how social class influences patterns of victimization and wrongful behavior, and (c) how the commonly held societal perception that crime comprises largely lower-class behaviors influences the way the criminal justice system deals with lower income populations. However, before examining these topics, we must

begin by examining the definition of *social class*, why social classes exist, and why they are an important aspect of free market societies.

What Is Social Class, and Why Is It Important?

When discussing social class, we frequently hear terms such as *upper class*, *middle class*, *lower class*, *working class*, and *underclass*. These terms attempt to differentiate social groups according to their access to economic, social, political, cultural, or lifestyle resources. Although such terms present an overly simplistic description that ignores the complexity and difficulties in defining social class, they do provide a starting point for discussing social stratification.

Economic resources consist of the wealth and/or income controlled by different social groups. The extent to which groups can exert political influence and/or cultural authority constitutes *social resources*, and the ability to directly shape the actions of governmental institutions such as political leaders or governmental functionaries, or indirectly through the exercise of power outside of government, constitute *political resources*. *Cultural capital* refers to the capacity of social classes to shape popular perception through access and control of mass media, education, and other platforms of public communication.

Finally, the phrase *lifestyle resources* refers to the degree to which group-based patterns of behavior and belief are valued or devalued within a society. These include such things as modes of speech, style of dress, attitudes and values, and preferred and/or available pleasures. As illustrated in studies of ghetto youth (see, e.g., Bourgois, 1995, and Wilson, 1987), the less individuals can look, talk, dress, and act in the approved white, middle-class manner, the less likely they are to be hired, even when they have the necessary skills for a job.

Attempts to understand social class typically fall into one of two types: (1) those following a *Marxian model* of social class and (2) those following a *Weberian model* of social class. Marxian models are concerned with locating individuals within distinct groups with respect to their relationship to the means of production, for example, those who earn some or all of their income through the ownership of productive wealth versus those whose only source of income is their ability to work for a wage. Because the social structure of modern industrial societies involves many more class locations than the simple distinction between owners and workers would allow, some analysts have developed the notion of *class fractions*; that is, although many people work for wages, some, such as corporate managers, are more closely linked to ownership structures than others, such as low-income wage workers. Considerable effort has been devoted to creating more precise definitions of where one class fraction ends and

another begins. This theoretically grounded approach to social class has been incorporated into sociological and economic research, but it has rarely been used within criminological research.

Criminological research typically treats social class from a Weberian perspective that views class as a matter of relative income levels. A more useful model for viewing social class is to understand it not simply as a matter of relative income but as the intersection of economic, cultural, and political resources that place social groups somewhere along a social class continuum ranging from the least to the most advantaged groups. At the highest level of this social class continuum in the United States are those groups that (a) earn large annual incomes; (b) control much of the country's wealth, in the form of real estate and material objects as well as in financial securities such as stocks, bonds, and hedge funds; (c) exert substantial influence over developing and implementing laws and governmental policy; (d) use wealth and power to shape the content of mass media; and (e) live the kinds of lifestyles that many people envy and would like to emulate. At the lower end are social groups that (a) earn relatively low annual incomes; (b) own little material property and almost no financial securities; (c) have minimal influence over government or media; and (d) have patterns of speech, dress, and behavior that are often viewed as disturbing or "dangerous" by better-off segments of the society. Between these two extremes are other groupings characterized by differing configurations of economic, social, and lifestyle resources that afford them fewer benefits than elites but more than the worst off.

The criminological significance of this differential distribution of resources is how it influences justice processes. Specifically, the social class system in America enables resource-advantaged groups to implement definitions of crime and justice that ensure elite-caused harms will rarely be treated as crime while harms more common among less advantaged groups—so-called street crimes—will be criminalized and vigorously punished.

Another important question to address is: Why do social classes exist? Like most of the world, the United States is based on a political-economic system organized around free-market competition. In these competitive market systems, some people win a larger share of the society's resources and assets than others. A number of reasons explain why some people may fare better in the competition for resources than others. A commonly held perception is that people obtain more because they work harder and sacrifice more; however, this is not always the case. Some people fare better than others because they are healthier or start life with more cultural and economic advantages than others. Others gain more because they have more hope and have not succumbed to the frustrations caused by the constant negotiation of the obstacles that society has placed in front of them. Although these represent some *individual* reasons for success or failure, they are not the cause of inequalities among large social groups.

For societies organized around economic competition, the division of society into social classes based on varying levels of material success is an inevitable, *structural* outcome. In the absence of measures that work to reduce social inequality, these differences tend to solidify into highly unequal class *systems*, in which people who are advantaged acquire more than the disadvantaged. The division of society into social classes also has a cumulative effect on economic disparity, whereby the more resources individuals bring to the game, the more resources they can win, in particular because economic expansion does not produce equal benefits to all social classes.

Between 1979 and 2005, for instance, the United States experienced a period of substantial economic growth. By 2005, however, the after-tax income of the richest 5% of the U.S. population had grown by over 80%, while the income of the bottom 20% of the population had declined by 1%. Although the middle fifth of the population, which represents the heart of America's hard-working middle class, did experience a 15% increase in net income during this time, this was still only about one fifth of the growth experienced by the top 5% of income earners (U.S. Census Bureau, 2006). In other words, according to a number of sources, it was clear that, during one of the strongest periods of income growth, income inequality increased.

In addition to shaping the distribution of financial wealth, economic stratification ensures the continuation of social class distinctions by determining access to *social capital*, that is, the nonmonetary resources and skills that enable individuals to do well in competitive societies. Children who grow up in financially advantaged homes in neighborhoods with high-quality schools, and who enjoy important developmental experiences such as early exposure to reading, writing, and analytic reasoning, will characteristically do better in school, pursue more advanced levels of education, obtain better careers, and earn more money over the course of their lives than people who grow up in households that could not provide these benefits. It is true that some individuals who are born poor succeed beyond expectations, while some who have every advantage fail; however, this is atypical. For most of the people, most of the time, their social class origins will shape much of their adult lives. The process of uneven competition ensures that wealth will concentrate within relatively small segments of the population, ensuring the continuation of social class differences.

Although an uneven distribution of wealth and cultural advantages is inevitable in any competitive-market society, the degree of inequality is the result of political forces. Governmental policies can either intensify or lessen class inequalities. Progressive taxation of income and capital gains can finance programs and policies that improve the chances of the people who are less well off while reducing income and wealth inequality. Alternatively, governments can pursue policies that make the poor poorer and the rich richer, such as regressive sales taxes and reducing the

amount of money spent on social programs that would close the wealth gap.

Exploring the Social Class–Crime Link

Whereas the origin of social classes is relatively clear, the effect of social class divisions on crime is less so. Annual reports of the characteristics of people arrested in the United States provide insight concerning gender, age, race, and ethnicity but tell us little about social class characteristics such as income, occupation, or residence. Consequently, the best information we have regarding the social class characteristics of the individuals who inhabit U.S. prisons and jails derives from surveys of prison inmates and, interestingly, the government provides very little money to fund research into these characteristics. The last detailed survey of prisoners serving felony sentences in state penitentiaries, who make up the majority of those incarcerated in the United States in any given year, was conducted in 1993. Apparently, the federal government has little interest in regularly gathering information about the class and other social characteristics of prisoners.

An examination of the U.S. correctional population leaves little doubt that most of the people serving time for criminal offenses come from the lower end of society's socioeconomic continuum. Government statistics show that criminal offenders in prison tend to be less well educated, more likely to be unemployed, and to earn far lower incomes than the general population. A 2002 survey conducted on inmates incarcerated in local jails revealed a similar pattern: Only about half of jail inmates were employed full-time at the time of their arrest, even though the national unemployment rate was below 5%, and over half of jail inmates earned less than \$15,000 a year (Bureau of Justice Statistics, U.S. Department of Justice, 2004).

Although these statistics may be somewhat skewed by the fact that better-off offenders who are charged with street crimes are more likely to avoid imprisonment, there is little reason to believe the degree of error is substantial. All one has to do is observe any urban police station or city court to know that very few middle- or upper class citizens are arrested and prosecuted for common street crimes. Clearly, the criminal justice net hauls in the poorest of the poor. What this tells us about the link between social class and criminal behavior, however, remains controversial. Some scholars argue that the disproportionate representation of poor people in prison is indicative of their overinvolvement in crime, whereas others suggest this disparity is the result of a criminal justice system that unfairly targets the poor.

The contradictory perceptions about the relationship between social class and criminality are, in part, the product of disparate research findings. There is no shortage of research studies that have examined this relationship; however, there is little consensus because of inconsistent findings and inclusive results. For example, some studies have

concluded that crime is more likely among people in higher social classes, whereas others have found criminality more prevalent among the lower classes. Some of these inconsistencies are traced to the different research methods used to study this relationship. These include different data collection methods; different measures of social class, crime, and criminality; different samples; and different methods of data analyses.

An examination of the past research reveals that the earliest of these studies (those conducted before the 1950s) tended to find more criminality among the lower classes than the upper classes. These findings in turn provided the foundation for numerous theories of crime and delinquency that attempted to explain why poverty was criminogenic, focusing on factors such as individual and cultural deficiencies, lack of opportunity, and differential (and harsher) treatment of individuals in poorer communities by the criminal justice system. Many of these theories, however, were only tenuously rooted in empirical research.

Although the social class–crime link was widely accepted, there were criminologists of the time who took issue with the methods that produced the correlation between social class and criminality. Most commonly, they argued that measuring crime through the use of official data (i.e., arrest data, prison statistics) presented a biased picture of crime. This measure of crime simply did not take into account the reality that many crimes go unnoticed or unreported, or for some other reason simply do not become known to those who wish to count them. This unknown and uncounted crime is referred to as *the dark figure of crime*. The problem, as they saw it, was that there was no way to determine whether accurately measuring the dark figure of crime would or would not show crime to be more broadly distributed. Some criminologists also argued that official measures of crime may actually better measure police practices than actual levels of crime; that is, in reality they may simply reflect, at least in part, the discretionary practices of police officers concerning whom to arrest and whom not to arrest, or a judge's propensity for sending particular offenders to prison while reserving alternative, community-based sanctions for others.

The development of self-report data in the 1950s intensified the ongoing debate. Researchers administered surveys to individuals randomly selected from the population and asked them to report their criminal behaviors. Although many of the earliest of these studies did not support the belief that lower social classes were more criminal, there was also enough research that found contradictory results to ensure that the issue would not be resolved. Furthermore, there were as many sociologists and criminologists who attacked the validity of self-report data as there were those who took issue with the validity of official measures of crime. Their argument was that there is no way to determine whether people in self-report studies are telling the truth about their criminal behavior. Doubters suggested that self-report surveys were better measures of

a participant's willingness to tell the truth about his or her criminality. They also speculated that people from the lower classes were underreporting their deviant and criminal behavior while those in the upper classes were overreporting, thereby artificially reducing the magnitude of the correlation between lower-class status and criminality.

Tittle, Villemez, and Smith (1978) reviewed 35 research studies that had examined the social class–crime link and concluded that there was an extremely small relationship, with the members of the lower classes exhibiting slightly more criminality. They also noted that this relationship had become smaller over the past four decades.

This by no means settled the debate; instead, research became the impetus for even more extensive and complicated empirical efforts. Much of these later efforts attempted to discover the conditions under which social class influences criminality. One set of studies attempted to determine whether the manner in which social class and crime were measured affects the likelihood of discovering a link between social class and crime. In terms of social class, several studies suggested that this relationship may exist only among people in the lowest economic strata, the group sometimes referred to as the *underclass*. These studies then measured social class by dividing populations into dichotomous categories such as welfare recipients and nonrecipients or, for school-age children, those who receive free lunches and those who do not. Other studies used a composite measure of social class, which often included education, occupation, and income. Still other studies used Marxian classifications of social class, conceptualizing social class in terms of an individual's (or his or her parents') relationship to the means of production—specifically, whether they owned some means of production or sold their labor for a wage. Still others expanded this fairly simple classification to include other variables, such as whether one has *control* over the means of production and/or *control* over the labor of others. The emphasis on control helped to distinguish between wage workers who have managerial positions and those who do not, an increasingly prevalent distinction in modern society.

Crime was also measured in a number of different ways in an effort to determine whether it conditions the social class–criminality relationship. For example, a number of studies have examined whether the negative relationship between social class and delinquency existed only for the most serious criminal offenses or the most frequent offenders. Also, the source of crime data was thought to have an effect on whether a relationship between social class and crime was uncovered. Some criminologists held that crime would be shown to be more prevalent among the lower class if official police data or court records are used to determine criminality. As previously mentioned, they argued that people from lower classes are more likely to underreport their criminal behavior on self-report surveys.

A number of studies also sought to determine whether demographic and environmental variables had important

conditioning effects on the class–crime relationship. For example, some studies examined whether the effect of social class on criminality was greater among blacks than it was for whites or among males than among females. Given the contradictory results of these research efforts, it would be difficult to suggest that the social class–criminality relationship was specific to a certain race or gender. Still another set of studies has examined whether this relationship was more likely in areas that were characterized as being more heterogeneous, more urban, or in higher status areas, and again produced mixed results.

Tittle and Meier (1990) reviewed the research literature that examined the relationship between socioeconomic status and delinquency and that attempted to specify whether any of the aforementioned conditions mattered. They concluded that there was little evidence that the link between social class and criminality existed under any of the conditions examined.

More recent and sophisticated studies have generally arrived at similar conclusions, although some studies did help clarify the relationship. For example, Wright and his colleagues (B. R. E. Wright, Caspi, Moffitt, Miech, & Silva, 1999) found that people in lower social classes experienced lower educational and occupational goals and more financial strain, aggression, and alienation, which in turn increase delinquency. Delinquency in the higher social classes, on the other hand, was the result of high socioeconomic status causing increased risk taking and social power, and diminished the commitment to conventional values, all of which then predispose these youth to delinquency. Dunaway, Cullen, Burton, and Evans (2000) examined the relationship between social class (measured in a variety of ways) and criminality (based on self-report surveys) and found that, among adults, the correlation was weak for less serious offenses. They did, however, find a class effect for violent offenses and among non-whites. This study was distinctive in that it measured adult criminality, a surprisingly underresearched population. In the end, the best conclusion that can be drawn about the relationship between social class and the commission of street crimes is that it tends to be weak and present only under certain specified conditions, and criminology researchers must continue to attempt to specify other circumstances that may influence this relationship.

What many of these studies do have in common is that most approached the definition of crime as being non-problematic instead of acknowledging crime as a multifaceted concept that includes crimes of the disadvantaged as well as crimes of the powerful. Unfortunately, the latter were, and still are, less apt to be considered. This is important, because if studies included offenses that powerful individuals are more likely to commit (e.g., insider trading), and that those in lower classes are in no position to commit, then there would be little question as to whether criminality would appear more evenly distributed across social classes than has traditionally been thought.

Moreover, it is only by including a wider variety of offenses that we can consider the social class–crime link as having been more completely and fairly tested.

So, although there has been little advancement toward settling the social class–street crime questions, the introduction of self-report studies has generally confirmed that criminality is more broadly and equally distributed across social classes than previously suspected. In fact, to date, these studies have consistently shown that nearly 90% of Americans have committed at least one crime for which they could have been sentenced to jail or prison. These findings may confirm that the use of official statistics means that we may not actually be measuring the level of crime or propensity for criminality but instead are measuring the decision-making practices of the criminal justice system (i.e., when to file an official police report, whom to arrest, whom to charge, and whom to send to prison).

Explaining the Relationship Between Social Class and Criminality

Although the relationship between social class and crime remains contested and unclear, it has not prevented the development of a number of theoretical explanations, which are formulated around the belief that poor people simply commit more serious crime. There are three types of explanations: (1) individualistic theories, (2) social interactionist theories, and (3) structural outcomes theories.

Currently, the most favored theories are those that suggest that higher rates of street crime among the poor are the product of family failings and personal morality. Collectively, these theories are considered *individualistic explanations* for crime. *Body Count* (Bennett, Dilulio, & Walters, 1996), an influential, conservative assessment of crime trends, argued that crime is the result of “moral poverty.” The authors claimed that high crime rates occur when families fail to impose clear moral understandings of right and wrong on the next generation. By focusing on “street criminals,” the authors make it clear that they are primarily concerned with the “moral poverty” of the poorer classes, not the moral poverty of the families that produce corporate and political criminals.

A second set of approaches suggests that if it were not for the discriminatory practices of the criminal justice system, the affluent would appear to be as equally criminal as the poor or, put in more positive terms, the poor would appear to be just as law abiding as the affluent. These *social interactionist* explanations contend that the criminals who show up in official statistics are disproportionately poor because (a) the justice system focuses on controlling poor communities, and (b) this practice increases the likelihood of future criminality by labeling residents of these areas, particularly young men, as criminals at an early

age. A typical example put forth is that the proportion of drug users among college students is no less than in that in poor communities, yet college students have a far lower risk of serving time as drug offenders than residents of poor communities because they are not the targets of “wars on drugs”—which are really wars on poor people. Although there is some merit to this approach, the question that remains is: Why does the criminal justice system do this? Is it merely a reflection of the discriminatory attitudes of the people who work in the justice system, or are they, as good workers, simply pursuing the goals set out for them by a broader political and economic system?

Finally, there are scholars who argue that poor communities suffer from higher rates of crime, in the same way that they suffer from disproportionate levels of other problems, such as alcohol and drug abuse, medical ailments, stress and hopelessness, not because of individual failings but because of the physical and emotional pressures of poverty and inequality. These *structural outcome* perspectives focus on the structurally induced discrepancy between the material desires of people in the poorer classes and their access to legitimate opportunities for fulfilling them. As initially described by Robert Merton (1938), this concept of *structural strain* contends that although desires for the “good things” in life are equally distributed across all social classes, the poor have fewer resources to obtain them. Some individuals resolve this pressure by resorting to illegal means to fulfill their culturally learned desires. When it comes to nonutilitarian crimes, such as interpersonal violence or drug use, structural outcomes models shift their focus toward how the daily frustrations and sadness of living poor can increase tendencies toward aggression or to self-medication with illegal drugs and alcohol as an escape from the hardships of daily life.

Regardless of the future outcome of the ongoing debate as to whether social class determines criminality in terms of the incidence or even prevalence of crime, it seems likely that social class at least shapes the types of crimes one commits. As the populist folk singer of the 1930s, Woody Guthrie, wrote, “Some men rob you with a six-gun, some with a fountain pen.” Whether one uses a six-gun or a fountain pen depends on the socioeconomic status of the individual. Although it is clear that those who occupy the most privileged and powerful positions certainly can and do at times engage in private crimes of greed, lust, or insanity, it is rarely possible for those in lower classes to engage in many of the illegal behaviors of the rich. Offenses such as price-fixing, embezzlement, and wire and securities fraud require jobs and circumstances possessed by people who have been exposed to advanced education and other social and cultural privileges.

The criminal justice system, however, is designed almost exclusively to control people who “rob you with a six-gun.” Those who commit corporate and political crime with a pen have little to fear from the justice system. In other words, social class not only shapes the type of crime

one can commit but also influences the likelihood of apprehension and severity of punishment. Many of the crimes in which people from the lower class participate, such as drug dealing, prostitution, and robbery, occur outside in the street, where detection is more probable. However, state-sponsored, corporate, and white-collar crime tends to occur behind the closed doors of offices and conference rooms, where detection is much more difficult. Also, when apprehension and threat of criminal prosecution do occur, individuals who possess economic and social capital are more likely to avoid punishment. They are able to post bail; employ high-priced, experienced attorneys; participate in developing their defense; and use their status in the community to decrease likelihood of conviction and/or severe penalties. Individuals in the lower classes, however, may not be able to raise bail and are more likely to be represented by an overworked, underexperienced public defender. Economically disadvantaged offenders may not even meet their attorneys until minutes before the trial, and, when they do, they are often persuaded to plead guilty in return for a less severe punishment.

Perceptions of Crime as a Lower-Class Phenomenon

Perceptually speaking, there appears to be a consensus among a large segment of the U.S. population that crime is largely the product of the behavior of lower-class populations.

If the relationship between social class and crime is not supported by research, why does the perception persist? In his seminal work concerning the *social reality* of crime, Richard Quinney (1970) noted that certain forms of crimes are embedded in the psyche of the American people; that is, when we think about crime, we tend to think of it in very narrow terms, often omitting the most prevalent crimes and, often, the people who cause the most harm. We tend to envision street crimes, such as murder, robbery, burglary, and assault, while rarely conceiving of white-collar, corporate, and state-sponsored crimes. Because street crime is often more likely to be carried out by people in the lower classes, and crimes of the elite—which generally do not occupy the public consciousness—are committed almost universally by people with economic, political, and social power, the theory of the social reality of crime neatly associates criminality with those on the lower rungs of the economic and social ladder. This remains true even in the face of the well-documented data demonstrating that crimes committed by the powerful cost the U.S. population more, both in terms of monetary and physical costs. Quinney (1977) suggested that this is so because the definition of what constitutes a crime is developed by those with economic, political, and social power and according to their own interests, whereas individuals without such power are more likely to have their activities defined as criminal.

Explanations for why the American public tends to have such a limited conception of crime are plentiful. The way crime is measured sheds light on one way that people obtain a narrow definition. There are three general methods used to measure crime: (1) official statistics, (2) victimization surveys, and (3) self-report studies. The last two methods measure various aspects of victimization and self-reported criminal behavior, and the first usually involves the Uniform Crime Reports, which relies on crimes known to the police to provide us with estimated crime rates. A crime become known to the police either because an officer discovers it or, more likely, because someone reports it to the police. As long as the police make a report of the crime, it is available to be counted and used in calculating crime rates. The caveat to this is that, in creating an overall crime rate, the Uniform Crime Report measures only eight offenses: (1) murder and nonnegligent manslaughter, (2) forcible rape, (3) robbery, (4) aggravated assault, (5) burglary, larceny-theft, (6) motor vehicle theft, (7) simple assault, and (8) arson. The first four are violent offenses, and the second four are property offenses. Because these offenses deal mostly with street crime, which the poor are more likely to commit, and omit a large number of offenses, many of which those in the upper economic strata are likely to commit, crime rates provide a skewed picture of crime.

Of course, news and entertainment media have also worked to present a picture of crime and victimization that is not necessarily rooted in reality. Crime has become a prominent theme in media content. One of the most noticeable aspects of media coverage of crime is that it tends to focus on the rarest of crimes. Images of relatively high-profile rapes, murders, and robberies are displayed on television screens throughout the day, throughout the country. Local newspapers and news shows typically adhere to the adage “If it bleeds, it leads.” News stories about the deviant and illegal practices of political, economic, and social elites receive no comparable attention unless they occur on a very large scale, as was the case with the collapse of companies such as Enron and WorldCom because of financial crimes.

However, media practices are not a complete explanation. As social actors, people play a role in, if not creating, then surely allowing the emergence and sustainability of a distorted image of crime. Stories about violent and gruesome crimes tend to capture public interest. This interest is part of the reason that the newspaper articles we read, and the news, movies, and TV shows we watch are dominated by crime stories. Indeed, some analysts argue that the media are simply responding to the desires of the public. They are a business and, like all businesses, their primary goal is to increase market share, advertising income, and profits. Therefore, if the public did not consume what the media presented, then the media would have to change what they offer or go out of business.

Public perceptions of crime are also a product of ideology. Many of our ideas about crime and criminality are

rooted in socialization and personal circumstances. Shaped by social background, religious principles, and political preferences, many people develop strong ideas about the causes and cures of criminal behavior relatively early in life. The extent to which people accept the common view of crime as a lower-class phenomenon is due in part to the fact that these views coincide nicely with the dominant rhetoric of religious, economic, and political leaders about the relationships among sin, poverty, and crime.

Finally, criminologists are complicit in creating an inaccurate depiction of crime. Criminology has historically focused almost exclusively on street crime in theoretical development and empirical research; that is, criminologists have devoted far more attention to describing and explaining crimes such as murder, burglary, robbery, and drug use than to white-collar offenses such as securities fraud, illegal price fixing, or other forms of elite deviance. It is only recently that a significant number of criminologists have started to empirically examine crimes of the elite.

Social Class and Criminal Victimization

Although there is some debate about the relationship between social class and criminality, the link between social class and criminal victimization is well-known and commonly accepted. Data provided by the National Crime Victimization Survey indicate that although the link between social class and victimization varies according to crime, overall, people who are less well-off tend to bear a greater burden as crime victims, particularly with respect to crimes of violence. The difference between rich and poor households as victims of property crime is less dramatic, although for the more serious crime of burglary, poor households face greater risks than rich ones.

The popular image of street crime is often that of the poor preying on the rich, but the reality of crime is that most people tend to commit crime within a relatively short distance of where they live. Thus, if the structural contradictions of poverty and inequality are more likely to result in individuals committing ordinary crimes, it means that the poor are also more likely to be the victims of street crimes.

Social Class, Crime, and Policy

Most problematic about the apparent misconception of the criminogenic nature of economic and social disadvantage is that policies implemented on the basis of this assumption are more harmful to the lower classes. Government policies can increase or decrease the criminogenic consequences of income and wealth inequality by choosing to pursue preventive or punitive justice strategies. Preventive strategies, such as preschool education of poor children, housing subsidies, and income support policies for poor families, will help reduce the negative effects of

inequality, lessening the number of low-income children for whom hopelessness becomes a pathway to delinquency, drug use, and maybe even adult crime. Punitive strategies, which are far more prevalent today, attack crime through get-tough tactics such as determinate sentencing, “wars” on crime and drugs, and removal of rehabilitation programs from prisons. This results in an increase in the number of people, mostly poor, who will be victims of the crimes committed by those who have become enmeshed in the justice system in ways that leave little option but to return to crime once they return to their communities.

Social class divisions are characterized by the asymmetrical distribution of political power, cultural authority, and wealth. Individuals whose money comes principally from investments or high-paying occupations have more opportunities to influence the formal institutions of government—including the justice system—than ordinary wageworkers, the poor, the unemployed, the young, or the undereducated. If you doubt this, examine the U.S. Senate, the Congress, or your state legislature, and you will find that most of the members tend to be wealthy, employed in high-status professions, or business owners, or possess some combination of these characteristics. At the federal level, one third of all senators and over one quarter of all congressional representatives are millionaires (Santini, 2004). The nonelite social groups that together comprise the vast majority of the American social landscape are almost entirely absent from the law-making process. As a result, the laws and policies that shape how we define crime are more likely to reflect the values, life experiences, and interests of the upper echelons of society.

Of course, laws and policies do not reflect the interests only of the upper echelons of society. Across social classes, there are many areas of consensus over the definition of crime. Both the rich and the poor agree that murder, rape, and burglary should be treated as crimes. It is where this consensus over the definition of crime breaks down that the greater power of the upper classes becomes apparent. For example, most Americans view deliberate acts of white-collar crime that lead to death or injury as being as serious as street crimes that lead to death or injury, and view corporate and political corruption as being as deserving of punishment as ordinary acts of theft. Lawmakers, however, come primarily from the strata of society that has the exclusive ability to commit white-collar crimes. As a result, the prosecution and punishment of white-collar, corporate, and political crimes has always been more lenient than the treatment of street crimes.

Whose Crimes Are More Harmful?

In addition to the conflict over who is more likely to commit crime, there is considerable disagreement about whose crimes cause the most harm. Past research fortunately has provided some fairly clear answers to this question, resulting in the following observation: Elite offenders pose a far

greater risk to health, life, and economic well-being than street criminals.

There are approximately 20,000 homicides in the United States every year; however, approximately 100,000 people die every year because of work-related illnesses and accidents, and almost 40,000 deaths occur because of inadequate medical care and unnecessary surgeries. Jay Albanese (1995) estimated that annual economic losses due to street crime are about \$10 billion, whereas the losses due to white-collar crime were nearly \$200 billion. As Jeffrey Reiman (2004) notes in his book, *The Rich Get Richer and the Poor Get Prison*, the latter figure is undoubtedly an underestimate. Reiman’s own calculations put the cost of white-collar crimes in the United States at over \$400 billion a year. He suggested that this figure also underestimates the true cost of white-collar crime. In fact, other researchers have estimated that the material and physical losses from white-collar and corporate crime may actually exceed \$600 billion.

If we ask, then, who is more likely to cause harm to society, it would appear that the upper and middle-class sectors pose the greatest danger to our health, life, and economic well-being. If we stick to the question of who commits the crimes targeted by the justice system, the picture remains unclear.

Conclusion

Social class has always been a critical component in the study of crime, criminality, and the criminal justice system’s responses. Although research is unclear as to the exact nature of the relationship, it seems evident that social class matters. It matters in determining who decides which harmful behaviors are criminalized and which are not. It matters when determining the severity of sanctions. It matters in the kinds of offenses one can commit and the quality of defenses one can mount when apprehended. It matters when one is looking at arrest records and prison populations. It matters when one is determining victimization patterns, and it matters in calculating the harm caused by crime. Ironically, where it may not matter is in determining who is more likely to be a criminal. Nevertheless, it matters, and because it matters, criminological research will, we hope, continue to explore the effects of social class on crime and, more important, its effect on justice, the one place where social class should definitely not matter.

VICTIMIZATION

BONNIE S. FISHER AND BRADFORD W. REYNS

University of Cincinnati

Victimization is the outcome of deliberate action taken by a person or institution to exploit, oppress, or harm another, or to destroy or illegally obtain another's property or possessions. The Latin word *victima* means "sacrificial animal," but the term *victim* has evolved to include a variety of targets, including oneself, another individual, a household, a business, the state, or the environment. The act committed by the offender is usually a violation of a criminal or civil statute but does not necessarily have to violate a law. Harm can include psychological/emotional damage, physical or sexual injury, or economic loss.

Victimology is the scientific study of victims. Victimologists focus on a range of victim-related issues, including estimating the extent of different types of victimization, explaining why victimization occurs to whom or what, the effects and consequences of victimization, and examining victims' rights within the legal system. Different domains of victimization are also of interest. Victimology is characterized as an interdisciplinary field—academics, practitioners, and advocates worldwide from the fields of criminology, economics, forensic sciences, law, political science, public health, psychology, social work, sociology, nursing, and medicine focus on victims' plight.

Types of Victimization

Personal Victimization

Personal victimization occurs when one party experiences some harm that is a result of interacting with an offending party. Personal victimizations can be lethal (e.g., homicide), nonlethal (e.g., assault), or sexual (e.g., forced rape). These victimizations can be violent (e.g., robbery) or nonviolent (e.g., psychological/emotional abuse). Examples of personal victimization also include domestic violence, stalking, kidnapping, child or elder maltreatment/abuse/neglect, torture, human trafficking, and human rights violations.

Property Victimization

Property victimization involves loss or destruction of private or public possessions. Property victimization can be committed against a person or against a specific place (e.g., residence), object (e.g., car), or institution (e.g., business). Encompassing offenses include burglary, arson, motor vehicle theft, shoplifting, and vandalism. Embezzlement, money laundering, and a variety of computer/Internet offenses (e.g., software piracy) are also property victimizations.

Estimating the Extent of Victimization: National Sources of Victimization Data in the United States

Uniform Crime Reports

One of the primary sources of annual victimization data is the Uniform Crime Reports (UCR). The Federal Bureau of Investigation (FBI) has compiled the UCR since 1930; it is the longest-running systematic data collection effort on crime in the United States. The UCR presents aggregate crime counts for personal and property offenses based on standardized definitions collected from jurisdictions in all 50 states; Washington, D.C.; and Puerto Rico. Crime counts are reported for the entire country, as well as for regions, states, counties, cities, and towns. Participation in the UCR is voluntary, with more than 17,000 city, county, and state law enforcement agencies participating, representing about 94% of the total U.S. population.

UCR crimes are divided into two categories: Part I and Part II offenses. Part I crimes are referred to as *index crimes* and include more serious offenses, which are subdivided into violent and property categories. Part I violent offenses are murder and nonnegligent manslaughter, forcible rape, robbery, and aggravated assault. Part I property offenses are burglary, larceny-theft, motor vehicle theft, and arson. Part II offenses are less serious offenses, including simple assault, drug offenses, and weapon offenses. In 1992, the FBI began reporting information on hate crimes. It also collects the UCR *Supplemental Homicide Reports*, which are the most reliable, timely data on the extent and nature of homicides.

The usefulness of the UCR as a measure of the “true” amount of victimization is limited, because it overlooks the *dark figure of crime*; that is, it includes only those crimes reported to and known by law enforcement and reflected in official crime statistics. Agency reporting practices, such as masking problems through manipulating or reporting incomplete crime counts, have also plagued the UCR. Another shortcoming is a lack of information about the victim or the context of the offense.

National Crime Victimization Survey

The National Crime Victimization Survey (NCVS) is another source of annual victimization data. Its precursor, the National Crime Survey (NCS), was initiated in 1973 by the U.S. Census Bureau and the Bureau of Justice Statistics with the goal of surveying a representative sample of members of the nation’s households regarding their victimization. The NCS was renamed in 1992 after an intensive methodological redesign (e.g., question wording

changes, addition of new crime types). Further changes in methodology (e.g., a new sample and method of interviewing) in 2006 do not allow its estimates and perhaps subsequent NCVS crime victimization estimates to be compared with previous years’ NCVS estimates.

Housing units are selected through a stratified multi-stage cluster sampling design. For 3 years and half-years, each household member 12 years and older from selected house units is interviewed. Victimization screen questions are asked and followed by a detailed incident report for each number of times the respondent reports the incident happened over the past 6 months.

Personal crimes include completed and attempted/threatened rape, sexual assault, robbery, simple and aggravated assault, and larceny with and without contract (e.g., pocket picking, purse snatching). *Property crimes* comprise household burglary, motor vehicle theft, and theft. Because it is a self-report survey, the NCVS does not collect information about homicides.

Among the strengths of the NCVS is the incident-level information that is used to assess the frequency, victim (e.g., sex, race) and incident characteristics (e.g., weapon use, victim-offender relationship, place of occurrence), and consequences of the victimization (e.g., injury, reporting behavior, economic loss). The NCVS collects information about incidents reported and not reported to law enforcement.

Topical supplements are periodically fielded and have included school crime (1989, 1995), workplace victimization (2002), stalking (2006), and identity theft (2008). Like all surveys, memory decay, forward and backward telescoping (i.e., the ability to remember things from the past [backward] or predict the future [forward]), and exaggeration by respondents are possible threats to the validity of the victimization estimates. Frequently victimized individuals, such as the homeless or those institutionalized, are not included in the NCVS.

National Incident-Based Reporting System

Another source of national victimization data is the National Incident-Based Reporting System (NIBRS). NIBRS is an incident-based reporting system of a wide variety of crimes known to law enforcement. The FBI created NIBRS in 1988 with the purpose of enhancing and improving the UCR to meet law enforcement needs in the 21st century. Like the UCR, participation in NIBRS is voluntary on the part of law enforcement agencies and is not based on a representative sample of crime in the United States.

NIBRS collects information about the nature of the offenses in the incident, characteristics of the victim and offender, types and value of property stolen and recovered,

and characteristics of persons arrested in connection with a crime incident. NIBRS has a number of improvements over the UCR. Additional crimes, such as drug offenses, fraud, kidnapping, and prostitution offenses, are included in NIBRS. NIBRS also collects data on the context of the incident, such as information on the relationship between the victim and the offender. NIBRS overcomes the UCR’s limitation of recording only the most serious offense with an incident; NIBRS records each offense within an incident. The complicated nature of the incident report, coupled with the strict guidelines and voluntary participation, has resulted in less than ideal levels of participation from law enforcement agencies.

Patterns and Trends in Victimization Rates

Consistent trends over time are evident from the UCR and NCVS. First, both sources have consistently reported that the annual property crime rate is larger than the violent crime rate. For example, the 2006 UCR reports that there were 3,334.5 property victimizations per 100,000 inhabitants of the United States, compared with 473.5 violent victimizations per 100,000. Second, both sources reported that crime rates have been declining over time. Figure 20.1 shows that the NCVS property crime rates have been steadily declining since 1973. Figure 20.2 shows that, since 1994, violent crime rates have declined, reaching the lowest level ever in 2005. The UCR reported that from 1996 to 2005, the violent crime rate decreased 26.3% and the property crime rate fell 22.9%.

Personal Victimization

The NCVS has consistently reported that assault is the most frequently occurring personal victimization. Of the two types

of assault, victims experience approximately three times more simple assaults than aggravated assaults. To illustrate, the 2005 NCVS estimated 13.5 simple assaults per 1,000 persons age 12 and older compared with 4.3 aggravated assaults per 1,000 persons age 12 and older. Robbery was the next most frequent, with 2.6 per 1,000 persons age 12 and older; rape was next at 0.03 per 1,000 persons age 12 and older. Murder was the least frequently occurring crime—an estimated rate of 5.7 per 100,000 inhabitants as reported by the UCR.

Demographic differences in personal victimization rates have also consistently been reported in the NCVS. In 2005, for example, persons of two or more races had the highest rates of violent victimization (83.6 per 1,000 persons age 12 and older), followed by blacks (27 per 1,000 persons age 12 and older), Hispanics (25 per 1,000 persons age 12 and older), whites (20.1 per 1,000 persons age 12 and older), and all other races (Native Americans, Native Alaskans, etc.; 13.9 per 1,000 persons age 12 and older).

Males had higher violent victimization rates than females. Males were almost 4 times more likely than females to be murdered in 2005. Males’ violent crime rate was 25.5, compared with females’ rate of 17.1 per 1,000 persons age 12 and older.

Victims of violence tend to be young and less likely to experience a violent victimization as they age. The age group most at risk was the 20–24 age group (46.9 per 1,000 persons age 12 and older), followed by the 16–19 group (44.2 per 1,000 persons age 12 and older), the 12–15 group (44 per 1,000 persons age 12 and older), the 25–34 group (23.6 per 1,000 persons age 12 and older), the 35–49 group (17.5 per 1,000 persons age 12 and older), the 50–64 group (11.4 per 1,000 persons age 12 and older) and, finally, the 65-and-older age group (2.4 per 1,000 persons age 12 and older). Interestingly, the relationship between age and victimization is very similar to the relationship between age and crime.

Property Victimization

Theft was the most frequent property victimization to occur in 2005, with 116.2 victimizations per 1,000 households; followed by household burglary, with 29.5 victimizations per 1,000 households; and motor vehicle theft, with 8.4 victimizations per 1,000 households. The overall property victimization rate was 154 per 1,000 households. The NCVS presents victimization information for a number of victim characteristics. As an example, the nature of one's housing (rent or own) shows that people who rent were victimized more than those who own (192.3 compared with 136.5 victimizations per 1,000 households). The location of the residence is also presented in the NCVS. People living in urban locations experience the most property victimizations (200 per 1,000 households), followed by suburban residents (141.4 per 1,000 households), and then rural residents (125.1 per 1,000 households).

Theories of Victimization

Relative to the field of criminology, which originated around the mid-18th century, victimology is a young field with roots in the late 1940s. Since that time, several generations of scholars have advanced its theoretical beginnings and promoted the reemergence of interest in the victim through a wide range of research questions and methods.

First Generation: Early Victimologists

First-generation scholarly work in victimology proposed victim typologies based on the offender–victim dyad

in a criminal act. Common to the ideas of these early victimologists was that each classified victims in regard to the degree to which they had caused their own victimization. These early theoretical reflections pushed the budding field of victimology in a direction that eventually led to a reformulation of the definition of victimization.

Hans Von Hentig

German criminologist Hans Von Hentig (1948) developed a typology of victims based on the degree to which victims contributed to causing the criminal act. Examining the psychological, social, and biological dynamics of the situation, he classified victims into 13 categories depending on their propensity or risk for victimization. His typology included the young, female, old, immigrants, depressed, wanton, tormentor, blocked, exempted, or fighting. His notion that victims contributed to their victimization through their actions and behaviors led to the development of the concept of “victim-blaming” and is seen by many victim advocates as an attempt to assign equal culpability to the victim.

Benjamin Mendelsohn

Benjamin Mendelsohn (1976), an attorney, has often been referred to as the “father” of victimology. Intrigued by the dynamics that take place between victims and offenders, he surveyed both parties during the course of preparing a case for trial. Using these data, he developed a six-category typology of victims based on legal considerations of the degree of a victim's culpability. This classification ranged from the completely innocent victim (e.g., a child or a completely unconscious person) to the imaginary victim (e.g., persons suffering from mental disorders who believe they are victims).

Marvin E. Wolfgang

The first empirical evidence to support the notion that victims are to some degree responsible for their own victimization was presented by Marvin E. Wolfgang (1958), who analyzed Philadelphia's police homicide records from 1948 through 1952. He reported that 26% of homicides resulted from victim precipitation. Wolfgang identified three factors common to victim-precipitated homicides: (1) The victim and offender had some prior interpersonal relationship, (2) there was a series of escalating disagreements between the parties, and (3) the victim had consumed alcohol.

Stephen Schafer

Moving from classifying victims on the basis of propensity or risk and yet still focused on the victim-offender relationship, Stephen Schafer's (1968) typology classifies victims on the basis of their "functional responsibility." Victims' dual role was to function so that they did not provoke others to harm them while also preventing such acts. Schafer's seven-category functional responsibility typology ranged from no victim responsibility (e.g., unrelated victims, those who are biologically weak), to some degree of victim responsibility (e.g., precipitative victims), to total victim responsibility (e.g., self-victimizing).

Menachem Amir

Several years later, Menachem Amir (1971) undertook one of the first studies of rape. On the basis of the details in the Philadelphia police rape records, Amir reported that 19% of all forcible rapes were victim precipitated by such factors as the use of alcohol by both parties; seductive actions by the victim; and the victim's wearing of revealing clothing, which could tantalize the offender to the point of misreading the victim's behavior. His work was criticized by the victim's movement and the feminist movement as blaming the victim.

Second Generation: Theories of Victimization

The second generation of theorists shifted attention from the role of the victim toward an emphasis on a situational approach that focuses on explaining and testing how lifestyles and routine activities of everyday life create opportunities for victimization. The emergence of these two theoretical perspectives is one of the most significant developments in the field of victimology.

Lifestyle Exposure Theory

Using data from the 1972–1974 NCS, Hindelang, Gottfredson, and Garofalo (1978) noticed that certain groups of people, namely, young people and males, were more likely

to be criminally victimized. They theorized that an individual's demographics (e.g., age, sex) tended to influence one's lifestyle, which in turn increased his or her exposure to risk of personal and property victimization. For instance, according to Hindelang et al., one's sex carries with it certain role expectations and societal constraints; it is how the individual reacts to these influences that determines one's lifestyle. If females spend more time at home, they would be exposed to fewer risky situations involving strangers and hence experience fewer stranger-committed victimizations.

Using the principle of *homogamy*, Hindelang et al. (1978) also argued that lifestyles that expose people to a large share of would-be offenders increase one's risk of being victimized. Homogamy would explain why young persons are more likely to be victimized than older people, because the young are more likely to hang out with other youth, who commit a disproportionate amount of violent and property crimes.

Routine Activities Theory

Cohen and Felson (1979) formulated *routine activities theory* to explain changes in aggregate direct-contact predatory (e.g., murder, forcible rape, burglary) crime rates in the United States from 1947 through 1974. Routine activities theory posits that the convergence in time and space of a *motivated offender*, a *suitable target*, and the *absence of a capable guardian* provide an opportunity for crimes to occur. The absence of any one of these conditions is sufficient to drastically reduce the risk of criminal opportunity, if not prevent it altogether.

Routine activities theory does not attempt to explain participation in crime but instead focuses on how opportunities for crimes are related to the nature of patterns of routine social interaction, including one's work, family, and leisure activities. So, for example, if someone spends time in public places such as bars or hanging out on the streets, he or she increases the likelihood of coming into contact with a motivated offender in the absence of a capable guardian. The supply of motivated offenders is taken as a given. What varies is the supply of suitable targets (e.g., lightweight, easy-to-conceal property, such as cell phones and DVD players, or drunk individuals) and capable guardians (e.g., neighbors, police, burglar alarms).

Empirical Support

Researchers commonly have used lifestyle exposure and routine activity theories to test hypotheses about how individuals' daily routines expose them to victimization risk. These theories have been applied principally to examine opportunities for different types of personal and property victimizations using diverse samples that range from school-age children, to college students, to adults in the general population across the United States and abroad. The data are generally supportive of the theories, although not all studies fully support the theories.

Third Generation: Refinement and Empirical Tests of Opportunity Theories of Victimization

Researchers' continued testing of lifestyle exposure and routine activity theories has generated supportive findings and critical thinking that has led to a refining and extension of them. Miethe and Meier (1994) developed an integrated theory of victimization, called *structural-choice theory*, which attempts to explain both offender motivation and the opportunities for victimization. This further refinement of opportunity theories of victimization was an important contribution to the victimology literature.

One of the first studies of opportunity theories for predatory crimes was conducted by Sampson and Wooldredge (1987), who used data from the 1982 British Crime Survey (BCS). Their findings showed that individual and household characteristics were significant predictors of victimization, as were neighborhood-level characteristics. For example, although age of the head of the household was an important indicator of burglary, the percentage of unemployed persons in the area also predicted burglary. Sampson and Wooldredge's multilevel opportunity model was among the first to test lifestyle and routine activity theories. Multilevel modeling of lifestyle exposure and routine activity theories continues to draw the attention of scholars seeking to test how both individual characteristics and macro-level ones—for example, neighborhood characteristics—frame victimization opportunities (see Wilcox, Land, & Hunt, 2003).

Victimization theories have been expanded to examine nonpredatory crimes and “victimless” crimes, such as gambling and prostitution (Felson, 1998), and deviant behavior such as heavy alcohol use and dangerous drinking in young adults (Osgood, Wilson, O'Malley, Bachman, & Johnston, 1996). The theories have also been applied to a wide range of crimes in different social contexts, such as school-based victimization in secondary schools (Augustine, Wilcox, Ousey, & Clayton, 2002), stalking among college students (Fisher, Cullen, & Turner, 2000), and even explanations of the link between victimization and offending (Sampson & Lauritsen, 1990). Other scholars have examined how opportunity for victimization is linked to social contexts and different types of locations, such as the workplace (Lynch, 1987), neighborhoods (Lynch & Cantor, 1992), and college campuses (Fisher, Sloan, Cullen, & Lu, 1998).

Fourth Generation: Moving Beyond Opportunity Theories

Work by Schreck and his colleagues suggests that antecedents to opportunity, such as low self-control, social bonds, and peer influences, have also been found to be important predictors of violent and property victimization (Schreck, 1999; Schreck & Fisher, 2004; Schreck, Stewart, & Fisher, 2006). Schreck, Wright, and Miller (2002) examined the effects of individual factors (e.g., low self-control,

weak social ties to family and school), and situational risk factors (e.g., having delinquent peers, having a lot of unstructured social time) on the risk of victimization.

Recurring Victimization

Distinguishing Between Repeat and Multiple Victims

People who experience two or more victimizations have been referred to as *recurring victims*. A *repeat victim* is one who experiences the same type of victimization two or more times in a given time frame. For example, if a house is burglarized, and burgled a second time later in the same month, the owner would be considered a repeat victim. A multiple crime type victim, or *multiple victim*, is one who is victimized by more than one type of offense over a period of time. For example, if someone experienced a personal victimization and a property victimization.

Characteristics of Recurring Victimitations

Studies on the topic of repeat victimization have confirmed that victimization tends to cluster. A growing body of research shows that repeat targets also experience a disproportionate amount of all crime victimizations. Studies that have used samples from the general population, college populations, and youth have reported that a small proportion of property or personal victims—individuals or households—experience a large proportion of all victimization incidents.

Two distinct patterns have emerged from study of the time course of repeat property and personal victimization research. First, if a second incident is going to occur, it is likely to occur relatively quickly after the first incident. Second, there is a period of heightened risk immediately following the occurrence of the prior incident that decreases over time. Studies of burglary, domestic violence, racial attacks, simple assaults, and sexual victimizations have reported these two patterns.

Recurring Victim Typologies and Theories

Much of the early work on recurring victims focused on victim typologies that sought to explain recurring victimization in terms of victim proneness. Similar to the early victimologists, Sparks (1981) developed a typology of repeat victimization that included the following elements: precipitation, facilitation, vulnerability, opportunity, attractiveness, and impunity.

Moving beyond typologies, Farrell, Phillips, and Pease (1995) examined the reasons for why repeat victimization occurs within the context of the offender's rational choices and routine activities, as well as their decisions to revisit the same targets more than once. In addition to detailing repeat victimization scenarios across a variety of crimes, these

authors advanced two important concepts to explain why offenders might be more likely to offend against already-victimized targets: (1) risk heterogeneity and (2) state dependence. The idea behind *risk heterogeneity* is that a victim possesses characteristics that make his or her subsequent victimization more likely—for instance, a house that is continually left unguarded and possesses no preventive devices, such as an alarm. *State dependence* refers to conditions created by a first victimization that allow for subsequent victimization—for example, the vandalism of a building with graffiti, whereby after the first tagging the target is made more attractive for subsequent taggers.

Lauritsen and Davis Quinet (1995) found support for both the state dependence and heterogeneity arguments in their study of young adults. The heterogeneity argument proposed is one in which persistent characteristics, such as temperament, stay with young people throughout their lives. The state dependence hypothesis, which asserts that a victimization incident changes something about the victim in some way that alters future risks, also was supported.

Hope and colleagues (Hope, Bryan, Trickett, & Osborn, 2001) focused on multiple victimization and reported a link between the risk of becoming a victim of a property crime and the risk of becoming a victim of a personal crime. Outlaw, Ruback, and Britt (2002) determined that individual and contextual factors were important predictors of repeat property, repeat violent, and multiple-type victimizations. Multiple victimizations were driven more by individual characteristics, whereas the repeat property and repeat violent victimizations were predicted by both individual characteristics and neighborhood settings. Perhaps one of the more valuable contributions of this study is the idea that repeat and multiple victimizations are affected by unique processes.

Effects and Consequences of Victimization

Physical Consequences

The physical consequences of victimization are often visible and range in seriousness from bruises and scrapes, to broken bones, to fatal injuries. Other, less foreseeable injuries, such as the threat of sexually transmitted diseases, can also be the result of a victimization incident. Forensic evidence collection can detect physical injury and other useful evidence to support the claim of a crime. For example, a specially trained medical nurse can perform sexual assault forensic examination and document vaginal–anal and oral injury from an alleged rape victim.

Psychological/Emotional and Mental Consequences

Emotional, psychological, and mental consequences of victimization may be less externally obvious but are just as serious as physical injury. Stress, depression, anxiety, and

other mental disorders are but a few that crime victims experience. There are distinct mental stages that follow a victimization incident: At first, victims feel shock and fear, and perhaps retreat from society; after this initial feeling of shock begins to subside, victims experience a range of emotions as they begin to readapt to their lives; finally, but with the consequences that victimization carries, victims attempt to reconcile and find a balance to allow them to pick up with their lives and routines where they left off. Persistent mental consequences such as acute stress disorder, posttraumatic stress disorder, and substance dependency, can occur.

Financial Consequences

The monetary costs of victimization to the victim are at times easy to calculate and at other times impossible to measure. Medical expenses, property losses, lost wages and legal costs are financial consequences that victims and their families must bear. Losses to the victim that are not as easy to estimate a dollar value for, but are nevertheless salient, are pain and suffering, and fear, among others. There are also financial consequences of victimization that society must bear: victim services, witness assistance programs, costs to the criminal justice system, and negative public opinion. In 1996, personal crime was estimated to cost \$105 billion annually in medical costs, lost earnings, and public program costs related to victim assistance. The estimated cost jumped to \$450 billion annually when the pain, suffering, and reduced quality of life that increased the cost of crime to victims were included (Miller, Cohen, & Wiersema, 1996).

The Victim–Offender Relationship

Victimization by Intimate Partners

The National Violence Against Women Survey comprises two national surveys administered in 1998 and 2000 to measure physical and sexual victimization and stalking in a sample of men and women in the United States. The survey reported that women experience more partner violence than men: 25% of women, compared with 8% of men, reported rape or physical assault in their lifetime. The majority of violence against women is committed by a spouse, former spouse, or other intimate partner: 76% of women who had been raped or assaulted since age 18 had been victimized by an intimate partner, compared with 18% of men. Women, regardless of victimization type, were also more likely than men to be injured during an assault: 32% of women compared with 16% of men. Victims of stalking are most often female, and most of these stalking victims (59%) are stalked by intimate partners, whereas male victims of stalking are most often stalked by strangers or acquaintances (Tjaden & Thoennes, 1998).

Victimization by Acquaintances

The NCVS presents data on the victim–offender relationship for certain crimes. A few examples from the NCVS demonstrate the prevalence of victimization by friends or acquaintances. According to 2005 NCVS estimates, male victims of violence were victimized by friends or acquaintances 36% of the time. Similarly, 39% of female victims of violence were victimized by friends or acquaintances. For rape and sexual assault, 38% of female respondents were victimized by friends or acquaintances; there were no recorded incidents of rape or sexual assaults of males by friends or acquaintances. Last, 18% of male and 39% of female victims had experienced robbery by friends or acquaintances.

Victimization by Strangers

The NCVS also provides information on victimization by strangers. As an example, the 2005 NCVS reported that 54% of male victims of violent crimes were victimized by strangers, compared with 34% of female victims. Sampson (1987) studied personal violence and theft by strangers to test an opportunity theory model of predatory victimization by examining how individual and community characteristics affect victimization risk. Violent victimization by strangers was experienced by 3.6% of the sample's males and 1.1% of the sample's females; 1% of the females experienced personal theft victimization by strangers, compared with 0.6% of the males. The most significant predictor of stranger victimization was alcohol use by the offender. Both individual and structural variables proved important in studying victimization by strangers, but thus far little research has been devoted to the topic.

Domains of Victimization

Victimization occurs in a variety of domains that modify the risks by altering criminal opportunity structures. Any setting can provide opportunities for different types of victimization.

Workplaces

Characteristics of specific workplaces structure worker routine activities and opportunity structures differently, and some increase employee risk of victimization more so than others. Lynch (1987) analyzed the relationship between worker routine activities and victimization at work. He reported that a person's routine activities at work, as well as the proximity of the workplace to potential offenders, significantly influenced the risks of worker victimization.

Schools

Schools are domains where young people congregate and, as such, provide unique circumstances as an environment for

victimization to occur. The 1995 supplement to the NCVS that focused on school victimization reported that 4.2% of the sample reported experiencing a violent victimization at school, and 11.6% had experienced property victimization. Because young people disproportionately represent both victims and/or offenders, routine activities theory would suggest that schools are places where victimization is likely to occur when guardianship is low. Astor, Meyer, and Behre (1999) found this to be the case—school areas such as parking lots, dining areas, and hallways were considered “unowned” by teachers and staff and were the locations where violence was most likely to occur.

College and University Campuses

College campuses are not ivory towers where students are insulated from risks of victimization but instead are another domain for victimization (Fisher et al., 1998). Although on-campus victimization of students is far from commonplace, for some types of crimes, such as property theft, college students are more at risk of victimization on campus than they would be off campus. Consistent with routine activities theory, Fisher et al. (2000) found that exposure to risky situations, in conjunction with a lack of guardianship and proximity to motivated offenders, placed college women at higher risk of being a victim of stalking. Women who lived alone had significantly higher odds of being stalked than women who did not live alone.

Places of Leisure

Places of leisure—bars and taverns, football stadiums, movie theaters, beaches, and many other places where strangers congregate that have domain-specific characteristics that dictate routine activities and behavior within that setting—are often domains of victimization. Roncek and Maier (1991) concluded that the number of bars and taverns had a significant positive impact on area crime. For example, assaults and robberies are almost 20% more likely to occur on blocks with bars or taverns than on those without such establishments. Patrons of these businesses may be more susceptible to having their property stolen if they are impaired by alcohol, may be more likely to get into a barroom brawl, or may be more vulnerable to hustlers.

Victims' Rights

Over the last two decades, the victim has begun to take a much more prominent role in the criminal justice process. One achievement is the *victim impact statement* (VIS), which is a way for the victim to communicate to the court what impact the victimization has had upon his or her life. The VIS is an opportunity for victims to describe emotional and financial costs they have incurred and voice their opinion as to what the appropriate punishment should

be. In 1987, the U.S. Supreme Court first addressed the issue of the VIS in capital cases. In the case of *Booth v. Maryland*, the court ruled that a VIS could not be shown to a jury in a capital case; in 1991, in the case of *Payne v. Tennessee*, the court reversed this decision to allow jurors to consider the VIS in its decision making.

There have been unsuccessful attempts to add a Victims' Rights Amendment to the U.S. Constitution to guarantee victims certain rights as victims participate in the criminal justice system. Amendments to state constitutions to include Victims' Rights Amendments have, however, been successful, with 33 states having such amendments. There has also been victims' rights legislation passed at federal and state levels since 1974, such as the 1996 Community Notification Act, also known as Megan's Law, requiring sex offender registration and community notification; the 2003 launch of the Amber Alert system; and the 2004 Justice for All Act, which grants rights to crime victims.

Victim Assistance

Victim assistance takes a wide variety of forms, from large federal government programs to smaller, grassroots efforts. Crime victim compensation programs exist in every state. The eligibility requirement varies across states, but examples of covered costs include medical and mental health expenses; lost wages; and in homicide cases, funeral expenses and loss of support for families. The enactment of the Victims of Crime Act in 1984 established the Crime Victims Fund, which allows state compensation programs to receive federal funding. Passage of the Violence Against Women Act of 1994 secured federal monies for criminal and civil remedies for domestic violence.

The civil courts are an arena in which victims can take action against offenders in an effort to recover damages for their losses. One type of victim assistance mandated by the courts is *restitution*: the process by which offenders pay back damages to the victim for the injuries received as a result of their victimization. A counterpart to restitution is victim *compensation*, in which case the state rather than the offender pays the victim for their losses.

Another avenue of assistance available to victims involves emergency aid, such as medical resources and treatment, a national telephone 24-hour crisis hotline where crime victims can obtain advice from trained specialists, and emergency protection or restraining orders. Counseling and advocacy, both short- and long term, and self-help groups are also available to victims.

Throughout the criminal justice process, there are many opportunities for victim assistance. During a criminal investigation, court advocates support victim's rights, and notification of pretrial release of the accused or input into the bond release decisions can be among the services offered to victims. During prosecution, orientation to the criminal justice system can be offered to the victim, as can consultation in plea bargains, accompaniment to court, and

employer intervention services. At sentencing, victims can be notified as to their right to submit a VIS. Postdisposition, the victim can be notified of the court's decision, submit a VIS for parole hearings, and receive notification of the status of the convicted person.

Peacemaking circles, whereby victim, offender, and their respective support systems and families meet to discuss what happened and how to restore the victim to his or her previctimization position, also have been used.

Comparative and International Victimology

Comparative Victimology

The study of victimology in the United States is generally considered to be narrower in scope compared with the broader nature of victimizations on which many scholars in the international community focus. Around the globe, there are serious forms of personal victimization on which researchers, policymakers, and advocates focus, including terrorism, war crimes, genocide, and femicide (the systematic killing of women). Other international offenses, such as cybercrime and human trafficking, frequently cross the borders of different countries.

International Sources of Victimization Data

Many countries across the globe measure victimization within their borders. Organizations such as the United Nations and the World Health Organization contribute to our understanding of victims and their plight. Two sources of international victimization data—the BCS and the International Crime Victims Survey (ICVS)—are among the most widely known.

British Crime Survey

The BCS is a nationally representative survey of residents of England and Wales that measures victimization, levels of crime, public fear of crime, and other criminal justice issues from year to year. Begun in 1982, the BCS is conducted by the British Market Research Bureau Limited on behalf of the Home Office. The survey was first administered in 1982 and included Scotland, which has since adopted its own crime survey, the Scottish Crime and Victimization Survey. The BCS was also administered in 1984, 1988, 1992, 1994, 1996, 1998, 2000, 2001, and has since been conducted every year.

One household resident age 16 or older from selection households is interviewed about victimizations he or she has experienced in the year prior, as well as detailed information about each incident (e.g., victim-offender relationship). Topics within the BCS include fear of crime, workplace victimization, and illegal drug use. Trends in the BCS indicate that overall victimization in England and Wales peaked in 1995 and has since declined to BCS launch levels (1982; Jansson, 2008).

International Crime Victims Survey

The ICVS is designed to measure victimization experiences and other crime-related subjects across the globe, with 30 countries participating in the latest wave and a total of 78 countries participating across the life of the survey. The ICVS was first administered in 1989 and was subsequently administered in 1992, 1996, 2000, and 2005; it is scheduled again for 2009.

One of the goals of the ICVS is to allow for international comparisons of crime and victimization across countries. Official statistics cannot be easily used, because legal definitions of crimes vary across countries and because so much crime is never known to authorities. The ICVS collects information on a variety of crimes, including theft of cars, theft from cars, motorcycle theft, bicycle theft, burglary, personal larceny, robbery, sexual offenses, assaults and threats, consumer fraud, corruption, hate crimes, and drug-related crimes. Overall victimization trends indicate a peak in victimizations in the mid-1990s and a decline since (Van Dijk, 2008).

International Violence Against Women Survey

The International Violence Against Women Survey (IVAWS) was developed to research the victimization of women around the world, in particular in developing countries. The IVAWS generates estimates of violence perpetrated by men against women, including physical assault; sexual assault; psychological/emotional abuse; and other crimes, such as human trafficking, femicide, and female infanticide. The IVAWS also measures the impact of violence on women and the steps taken after victimization to seek help. The survey methodology was developed on the basis of the one used by the ICVS with the goal of making international comparisons of the prevalence and risk factors of violence against women. Methodological issues include cultural differences between countries, translation issues, interviewing methods, and subjectivity (e.g., what is a sexual assault in one country may not be considered as such in another country). Data were collected from 2003 through 2004 in 11 countries, including Australia, Costa Rica, Italy, the Philippines, and Poland (Johnson, Ollus, & Nevala, 2007).

World Crime

Risks of violent victimization around the world are clustered among countries within certain regions of the globe. Africa, Central America, South America, the Caribbean, and eastern Europe have the highest homicide rates in the world. On the basis of information from 110 countries, the countries in which one is most at risk for homicide are Swaziland, Colombia, and South Africa, with the lowest risks being enjoyed by Myanmar, Cyprus, Morocco, and Israel (Van Dijk, 2008). Compared with other countries, the United States is in

the middle range for homicide risks, but if only developed nations are examined, it quickly rises to the top of the list.

For the crime of assault, the most dangerous region is Africa, with North America and Oceania (Micronesia, Melanesia, and Polynesia) as distant contenders. The most risky countries for assault are South Africa, Zimbabwe, and Swaziland, with Mexico, the Philippines, and Turkey being the least risky. Papua New Guinea, Colombia, Nigeria, and India are ranked the most risky countries for women to be sexually assaulted, whereas Azerbaijan, Hong Kong, and the Philippines are the least risky. Violence against women by intimate partners is estimated to be the most prevalent in the Middle East, Africa, and Asia (Van Dijk, 2008).

For property crimes, the places in the world that are most at risk are not generally the same as for violent victimization. Car theft occurs most often in England and Wales, New Zealand, and Portugal, with residents of Austria, Japan, and Germany experiencing it the least. Risks of motorcycle theft are highest in Italy, England and Wales, and Japan, and lowest in Mexico, Luxembourg, and Bulgaria. Risks for having one's bicycle stolen are greatest in the Netherlands, Denmark, and Finland. Burglary risks are highest in England and Wales, New Zealand, and Mexico and lowest in Sweden, Spain, and Finland. The risk of being a pickpocketing victim is highest in Greece, Estonia, and Ireland and lowest in Japan, Mexico, and New Zealand (Van Dijk, 2008).

IMMIGRATION AND CRIME

HOAN N. BUI

University of Tennessee at Knoxville

Concerns about the connection between immigration and crime have a long-standing history in the United States, dating back to colonial times. Increased immigration was believed to be associated with increased criminal activity. Negative perceptions of new immigrants were exacerbated by the fact that the British frequently shipped convicts on a large scale for white servitude in certain colonies where labor was needed. The colonists were also disturbed by people who fled to United States to escape the consequences of misbehavior committed in their homeland; these undesirable free immigrants were believed likely to become troublesome citizens. As the practice of transportation of convicts by the British came to an end with the Revolutionary War, new concerns arose regarding European immigrants who came to the United States after experiencing hunger and hardship of long wars in their country of origin. In addition, belief remained that several European governments continued sending felons to the United States. Thus, perceptions arose that new immigrants disproportionately engaged in crime because they belonged to the criminal class or because they were unable to adjust to new conditions of American life.

The perception about the positive relationship between immigration and crime also appears to be motivated by anti-immigrant, xenophobic sentiments. Negative stereotypes of newcomers often ensue from periods of increased

immigration, in particular during economic downturns or when new immigrants differ substantially from the natives in cultural, racial, and/or ethnic backgrounds. In recent years, concerns about negative consequences of immigration to the United States have been based on the assumption that immigrants have caused many social problems to U.S. society, including changing the American ways of life, depleting welfare resources, increasing unemployment among native-born persons, causing housing shortages, overwhelming school and health care systems, and undermining the existing social order. The media also have blamed immigrants for the drug problem in the United States, accusing illegal immigrants of flooding drugs into the country.

These perceptions about immigrants have had important policy implications. Numerous policies aimed at reducing the flow of immigration, restricting immigration from certain countries, limiting social benefits for immigrants, or increasing penalties for immigration violations have been implemented throughout history in response to these negative perceptions. This chapter examines the immigration–crime link, beginning with an overview of U.S. immigration history. This is followed by discussions of theories about the relationship between immigration and crime, research findings about patterns of crime and factors affecting crime among immigrants and their children (the second generation), and crime victimization experienced by immigrants.

U.S. Immigration: A Historical Overview

Throughout history, U.S. immigration policy has been shaped by two contending views: One advocates that the United States should serve as a refuge for the world's dispossessed; the other believes that immigration policy should benefit the United States by granting admissions for people who add to the economy and society but excluding those who may become a burden (Fix & Pastel, 1994). Many of the core elements of the U.S. immigration policies existed in the colonial era, but comprehensive immigration policies under the form of federal laws did not emerge until the end of the 19th century. In regard to federal laws, regulations of immigration to the United States can be divided in two distinct periods. The first period was characterized by immigration restrictions, beginning with the Chinese Exclusion Act of 1882, which, among other provisions, suspended the immigration of Chinese laborers and removed the rights of Chinese immigrants to become citizens. From 1822 to 1965, several other immigration policies were implemented to define the quality and quantity of persons who could be admitted to the United States as immigrants. Criminals, prostitutes, physically and mentally ill people, and those who were illiterate were barred from entering the United States. National-origin exclusions were expanded to the Japanese in 1907 and to all Asians in 1917. The quantitative restriction on immigration was imposed in 1924 under the National Origin Act, which determined admission quotas for European countries based on the proportion of each country's population present in the United States during the 1890 census. Consequently, a majority of immigrants to the United States before 1965 hailed from European countries.

A new era characterized by a shift toward a more liberal immigration policy began in 1965, with the Immigration and Nationality Act (also called the *Hart Cellar Immigration Reform Act of 1965*). The national-origin quota system was replaced by a system that gave admission preference for two categories: (1) relatives of U.S. citizens and lawful permanent residents and (2) people with job skills deemed useful in the United States. The law also created different admission caps for countries in the Eastern and Western Hemispheres. As a result, the number of female immigrants, as well as the number of immigrants from Asia and Mexico, increased substantially. Three other major immigration policies were implemented between 1980 and 1990, representing a trend toward more open immigration. First, the Refugee Act of 1980 created a comprehensive refugee policy and set up a permanent and systematic procedure for admitting refugees. Second, the Immigration Reform and Control Act of 1986 addressed the issue of illegal immigration. It sought to enhance enforcement by increasing border enforcement and instituting employer sanctions for knowingly hiring illegal aliens. The law also created two amnesty programs that gave certain types of unauthorized aliens a legal status in the United States. Under these amnesty programs, almost 3 million people

illegally living in the United States became lawful permanent residents. Third, the Immigration Act of 1990 increased legal, employment-based, and skill-based immigration. It tripled employment-based immigration with its focus on skills needed in the U.S. economy. A new trend emerged in 1996, however: The Illegal Immigration Reform and Immigrant Responsibility Act of 1996 addressed border enforcement and the use of social services by immigrants. The law increased the number of border patrol agents, introduced new control measures, and reduced government benefits to immigrants.

Since 1820, the year when immigration statistics first became available, the numbers of immigrants coming to the United States have steadily increased, even during the period of immigration restrictions. The number of foreign-born persons admitted to the United States as legal permanent residents in 1820 was less than 10,000, but this number has been increased to more than 1 million since 2000. These legal permanent residents are officially defined as immigrants. Besides legal immigration, illegal immigration is an important issue in the United States. Over the years, seasoned workers from many countries have been recruited to work in the United States under nonimmigrant visas for a limited period of time. A major source of illegal immigration has come from temporary workers and tourists who overstay their nonimmigrant visas. Foreign nationals who illegally enter the United States by crossing the border have also contributed to the illegal immigrant population. By 2006, the foreign-born population in the United States (including both legal and illegal immigrants) reached 37.5 million, accounting for 12% of the U.S. population. The illegal immigrant population was estimated at 12 million, or one third of the foreign-born population. In this chapter, the term *immigrants* refers to foreign-born persons who are admitted to the United States as legal permanent residents or those who are allowed to resettle in the United States but do not have yet a permanent resident status. This group is also considered the first immigrant generation.

Theories on the Relationship Between Immigration and Crime

Several theories have been used to explain the relationship between immigration and crime as well as patterns of criminal behavior in different immigrant groups and generations. These theories focus on different factors considered important in shaping individual behavior and immigration resettlement experiences.

Self-Selection Theory

Low levels of criminality among early immigrants have led to the assumption that these immigrants were self-selected economic individuals who had a low criminal tendency. This is known as *self-selection theory*. Advocates of

self-selection theory argue that because these immigrants left their homeland and came to the United States for economic opportunities, most of them were hard working. Due to their interest in long-term advancement, they behaved themselves and avoided getting into trouble with the law. Recently, Butcher and Piehl (2005) used the model of labor market outcomes to explain low levels of criminality among immigrants who came to the United States after 1965 and to support the self-selection hypothesis. According to Butcher and Piehl, some occupational skills are transferable across countries but translate into different earnings across places. Thus, low-earning skills in one country may be translated into a very different level of earning in other countries. When possible, immigrants will choose to move to a country where their earnings will be higher, and the economic outcomes can serve as a protection against criminal activities.

Social Structure Theories

Social structure theories focus on socioeconomic structures that shape economic opportunities, which in turn influence criminal tendency. According to *strain theory*, developed by Merton (1938), material success depends on education and job opportunities, which are not equally available to everyone. When legitimate opportunities are not available, crime can be an innovative alternative to achieve material goals. Because many new immigrants are unskilled and poorly educated, and because economic opportunities do not penetrate urban ghettos, where many new immigrants resettle, crime is likely to be an option. *Social disorganization theory*, developed by Shaw and McKay (1942), emphasizes the adverse social conditions in urban ghettos that facilitate the breakdown of community institutions and social control mechanisms. According to this theory, poverty, high levels of population turnover, cultural heterogeneity, and the presence of a large number of adult criminals weaken social control and foster delinquency. Immigration increases crime because it causes social change and creates social disorganization that makes social control less effective.

Culture-Based Theories

The *subculture-of-violence theory*, developed by Wolfgang and Ferracuti (1967), suggests that as poor people adapt to their structural conditions, violence can become a normal and expected means of dispute resolution in deprived and disorganized communities. Because new immigrants are more likely than native individuals to live in these areas, it is assumed that they are more likely to engage in violent crime. *Culture conflict theory*, on the other hand, emphasizes the difference between U.S. laws and cultural traditions that immigrants brought from their home countries. According to Sellin (1938), criminal law reflects the values and interests of the dominant groups, and the system of values and norms among immigrants may be quite different. When the cultural

codes of immigrants are in conflict with those of the host society, the behavior of immigrants will be labeled deviant or criminal. Thus, the conflict of cultures is a reason for crime among immigrants.

Acculturation and Assimilation Perspectives

Acculturation, or *cultural assimilation*, refers to changes in attitudes and/or behaviors as a result of contact with other cultures. Among immigrants and their children, cultural change occurs on a number of dimensions, including the language, cultural beliefs, values, behaviors, and one's loyalty and sense of belonging to the host culture and one's culture of origin. The classic assimilation model proposed by Gordon (1964) posits that acculturation to and acceptance by the host society are prerequisites for social and economic mobility. The acquisition of English proficiency, higher levels of education, and valuable new job skills can ease the adaptation process and improve the immigrants' chance of success in the U.S. economy. A lack of acculturation is considered a factor that contributes to crime and delinquency among immigrants who lack knowledge of new legal norms and thus the ability to adapt to the new economy.

Research findings about low levels of crime and delinquency among the foreign-born have challenged the classic model of assimilation and suggest that acculturation also has negative consequences. Recent literature indicates that the longer immigrants and their children live in the United States, the more they become subject to economic and social forces, such as high rates of family disintegration and substance use, that are found to be associated with criminal behavior among the natives. In addition, with greater time and socialization in U.S. institutions, neighborhoods, and youth culture, the children of immigrants increasingly adopt behavioral norms of the host society, including health and risk behaviors. Acculturated adolescents are likely to challenge the cultural mandate regarding parental control and authority when they experience conflicting sets of expectations from their foreign-born parents and persons from the larger society with whom they are in most immediate contact. Thus, acculturation can facilitate delinquency by weakening parent-child relationships and diminishing parental authority.

Segmented Assimilation Perspective

The *segmented assimilation perspective* was developed with a focus on the changing U.S. economy and labor market and how they affect the experience of recent immigrants who have come mostly from Asia and Latin America. According to Portes and Zhou (1993), new immigrants and their children experience different adaptation processes based on the characteristics of the U.S. population in which they are integrated. Consequently, greater exposure to American culture may be associated with mixed adaptation outcomes. Depending on the type of human capital (education and

skills) and social capital (social resources and supportive opportunities) that different immigrant groups possess, one path will lead to the assimilation of the immigrants and their children to the middle-class majority. An opposite type of adaptation caused by poverty and racial segregation will lead to downward mobility and the assimilation of immigrants and their children into the inner-city underclass. The exposure to and contacts with various types of social problems commonly found in lower class neighborhoods will facilitate crime and delinquency among children of immigrants. Adherence to the traditional values and retention of ethnic identity will lead to the third path of adaptation, with rapid economic advancement and the preservation of values and solidarity among immigrants. Communities of co-ethnic people can supply to new immigrants the types of social capital that can protect against criminal behavior by increasing economic opportunities, enforcing norms against divorce and family disruption, and reinforcing parental authority over children.

Relationships Between Immigration and Crime

The link between immigration and crime became a research topic at the turn of the 20th century, after immigrants from Europe came to the United States in large numbers. The immigration–crime relationship was not a major research topic before this because the trend of immigration was slow during this period and because it was believed that large segments of European immigrants coming in the early 20th century were already assimilated to U.S. society. With the open-door policy under the Immigration and Nationality Act of 1965, new immigrants again arrived in the United States in numbers not seen since the turn of the 20th century. Post-1965 immigration, which included large numbers of Asians, Afro-Caribbeans, and Latinos, renewed research interest in the topic partly because of increased public debates about the costs and benefits of immigration and partly because of the coincidence of two social phenomena: (1) the arrival of new immigrants and (2) the rise in crime rates in the 1970s and the 1980s. There were also concerns about low levels of labor market skills among new immigrants, especially those who arrived through clandestine channels and legal loopholes. Early and recent studies produced different findings but did not show strong evidence about the causal effects of immigration on crime. Instead, they indicated the effects of various socioeconomic factors on criminal behavior among immigrants.

No Negative Effects of Immigration on Crime

Several early and recent studies did not find evidence about the negative effect of immigration on the crime problem. Findings from three early studies, including those of the Industrial Commission (1901), the Immigration Commission (1911), and the National Commission on Law Observance and Enforcement (also popularly known as the Wickersham

Commission, 1931–1932), indicated that, on the macrolevel, cities with a high proportion of foreign-born persons did not necessarily have higher crime rates than cities with a lower proportion of foreign-born persons. On the microlevel, foreign-born whites were viewed as less criminal than U.S.-born whites because they had lower rates of incarceration. Court records also showed that foreign-born people were less likely than native-born people to be found guilty of crime. Research in recent years has provided similar findings, showing that neighborhoods with large concentrations of the foreign-born had lower levels of violence than those with smaller proportions of foreign-born residents. Cities near the U.S.–Mexico border, such as El Paso, Texas, and San Diego, California, have been ranked as low-crime areas, and cities with concentrated immigrant populations, such as New York, have been considered among the safest places in the United States. Research on several ethnic–racial groups perceived as having high levels of crime provided further evidence for a low level of crime among immigrants. Compared with U.S.-born Mexican Americans, foreign-born Mexicans in the United States have lower rates of arrest, conviction, and incarceration. In Miami, Florida, Haitian and Latino immigrants are underrepresented in homicide relative to their group sizes. Homicide rates among Haitians are much lower than those among U.S.-born blacks in the same area and, in some cases, even lower than those among U.S.-born whites. Mariel refugees, who came to the United States from Cuba in the 1980s, were rarely overrepresented among homicide offenders. Although they were likely to be involved in acquaintance homicides, there is little evidence that they were disproportionately involved in stranger homicide or that they were unusually violent, as suggested by dominant themes in popular stereotypes.

Although most of the research just discussed did not explain the reason for the low levels of arrest and conviction among foreign-born immigrants, a recent study conducted by Butcher and Piehl (2005) suggested that the self-selected nature of immigrants explains their low levels of criminality. They found that recent immigrants from all racial and ethnic backgrounds had lower levels of education but that they also had substantially lower levels of incarceration than natives, even during the time period when institutionalization expanded. In 2000, among men ages 18 through 39, the group that made up the vast majority of the prison population, the foreign-born had an incarceration rate (0.7%) that was 5 times lower than that of the native-born (3.5%). After finding no support for other explanations (e.g., increased deportation and deterrence), Butcher and Piehl concluded that immigrants were self-selected from among those with a low criminal propensity.

Age and Gender Structure and Crime Among Immigrants

Not all studies have found low levels of crime among immigrants, however. Because young males have higher crime rates than other age and gender groups, the large

proportions of young males in particular immigrant groups can contribute to high levels of crime in these groups. Incarceration rates among immigrants from Ireland and Germany in the 1850s were more than 10 times higher than those among the native-born, and these two immigrant groups had a large proportion (60%) of young males. In the study conducted by the Industrial Commission (1901), foreign-born whites had an overall imprisonment rate that was higher than the rate among U.S.-born whites but lower than the rate among U.S.-born blacks. However, among people aged 20 to 45, imprisonment rates among the foreign-born were only 15% higher than those among the native whites and, among the adult male population (age 21 or older), foreign-born whites had lower imprisonment rates than native-born whites. Research on Mexican immigrants in the 1930s suggested that a large proportion of young males was a reason behind the high offending rates in this group. Recent studies also have indicated the effect of age and gender on crime rate among immigrants. In Miami, homicide rates increased shortly after Afro-Caribbean immigrants (including Mariel Cubans, Haitians, and Jamaicans) arrived in the 1980s. In late 1990s, when these immigrant groups grew in size, became older, and had low proportions of young males, their homicide rates rapidly declined, dropping below the average national rate for cities of Miami's size (Martinez & Lee, 2000). According to Hagan and Palloni (1998), Hispanic immigrants are disproportionately young males who, regardless of immigration status, are at a greater risk of criminal involvement. When age and gender are taken into account, the involvement of Hispanic immigrants in crime is less than that among the native-born.

Socioeconomic Conditions of Immigration Resettlement and Crime

Negative experience with emigration and resettlement are considered factors that contribute to adaptation outcomes. Problems faced by immigrants in their country of origin before emigration and their negative experience during the process of immigration and resettlement, including physical torture, posttraumatic stress disorder, discrimination, and alienation, can be associated with the tendency to commit crime. Research indicates that Southeast Asians in the United States were more likely than native whites to engage in crimes that produced financial gains, such as theft, auto theft, and petty theft. Youthful crime among Southeast Asians has been considered as emerging out of the cohort that first arrived in 1980; many of them were alienated youth who had emigrated without parents, suffered from posttraumatic stress disorder caused by hardship in the process of immigration, and experienced adaptation problems.

Crime rates among immigrants also vary across locations, even for the same racial and ethnic groups. Among Puerto Rican newcomers, those living in New York City tend to have higher rates of homicide, whereas those living

elsewhere have rates comparable to those among native whites. In rural areas in Texas and California, where the Mexican populations are large, the criminality of foreign-born Mexicans is relatively lower than that among the native-born. In more urban communities, Mexican immigrants have relatively higher crime rates. The role of immigration in contributing to high levels of crime in some locations of concentrated immigration is considered limited, but economic deprivations and social disorganization are seen as main factors. In a well-known study of delinquency in urban areas conducted in Chicago in the early part of the 20th century, Shaw and McKay (1942) found high arrest rates for delinquency in areas with large concentrations of immigrants. As these immigrant groups moved from poor areas into places where crime rates were lower, the groups' arrest rates also fell. Recent research also has shown that high levels of violent crime among Latinos in major cities in California were associated with the existence of local alcohol outlets and other vice-related businesses.

Cultural Conflicts and Crime Among Immigrants

Besides different levels of criminality, patterns of crime committed by immigrants and native-born individuals also differ. Early research showed that, for gainful offenses (or property offenses, including robbery, burglary, theft, and fraud), native-born people had higher conviction rates than foreign-born groups. For offenses against public policy (e.g., carrying weapons, intoxication, vagrancy, and truancy), the foreign-born had greater conviction rates than the native-born. The formal criminal charge rates for homicide and aggravated assault among the foreign-born approached those among native-born whites, and in some locations were even slightly higher. Different patterns of offending were also found across national groups. The Italian group stood out for high conviction rates for homicide, rape, and kidnapping; Russians for larceny and receiving stolen goods; and French for offenses against chastity and for prostitution. Mexicans had higher arrest rates than native-born whites, but the vast majority of Mexican arrests were for public order misdemeanors, such as vagrancy, possession of marijuana, and public intoxication. Asian immigrants had consistently low arrest rates, except for gambling. Foreign-born Chinese had the highest arrest rate of any ethnic group in San Francisco, and gambling in particular led to unusually high arrest rates among Chinese in San Francisco and other major cities.

Different patterns of crime between foreign-born groups and native-born groups, and among different national groups, suggest the impact of cultural conflicts on criminal behavior. The Wickersham Commission (1931) identified two factors that brought early immigrants into conflict with the law. First, immigrants' ignorance of the language (English) was a source of confusion and misunderstanding about laws, regulations, and customs in the United States.

Many immigrants were arrested for unknowingly violating ordinances that regulated licenses and provided for sanitary and fire prevention inspections. Second, immigrants brought with them a well-defined set of habits of thought and behavior, which had been built up in an environment that was entirely different, in regard to law and custom, in the United States. During the Prohibition era, U.S. laws about gambling; prostitution; and the manufacture, sale, and consumption of beer, wine, and liquor were entirely different from those in the countries from which the immigrants came. Their lifetime habits and experience in the country of origin did not readily prepare them for change. Some immigrant groups also held a strong belief in personal and family pride and were accustomed to the practice of men's use of violence, including killing, to wipe out any stain brought upon the honor of their women. Because of the availability of weapons that many immigrants carried to protect personal safety in certain locations, flaring anger over issues of honor often inevitably led to fatal endings. This was considered one of the primary reasons for the high percentage of violent crime among the foreign-born.

In recent years, culture conflicts were also considered a factor contributing to domestic violence in immigrant families. Gender inequality, women's subordination to men, and cultural and legal norms that give men the right to control women are considered factors contributing to domestic violence. In the United States, cultural and legal norms that support gender equality as well as economic opportunities for women often change the power dynamics within immigrant families. Being threatened by the perceived or actual loss of power, but not familiar with the prohibition of domestic violence in the United States, often facilitates immigrant men's use of violence against their wives or female partners.

Crime in the Second Generation

Research evidence suggests that although immigrants do not disproportionately engage in criminal activity, the crime problem is associated with the second generation (i.e., U.S.-born children of foreign-born immigrants), whose members have higher rates of arrest, charge, and incarceration than those among foreign-born immigrants. Sometimes, the levels of criminality among members of the second generation are even higher than those among the native-born of native parentage (third and higher generations). Patterns of offense committed by members of the second generation also shift away from those found among their foreign-born parents toward those among the native-born. Early studies indicated that public intoxication was the most common offense among foreign-born whites, but sons of the foreign-born were arrested and charged with serious crime against persons and property (e.g., homicide and fraud) very much more frequently than their foreign-born parents. In regard to robbery, arrest rates among members of the second generation were 4 times

greater than those among their foreign-born parents and even surpassed arrest rates among U.S.-born whites of U.S.-born parents. In regard to incarceration, U.S.-born whites of foreign-born parents (the second generation) had an imprisonment rate that was 3 times greater than the rate among U.S.-born whites of U.S.-born parents. Questions about organized crime among immigrants also emerged during the Prohibition era. Limited data showed that comparatively few of the gangsters were foreign-born, but a high proportion of them were the sons of foreign-born parents reared in the slums of American cities. Recent research also shows that members of the second and third generations were much more likely than their first-generation counterparts to engage in substance use and to commit property and violent crimes, including homicide.

Although the second generation has an overall higher level of criminality than individuals among their foreign-born parents, the gap in criminality between the first and second generations varies across racial groups, locations, and types of offense. Recent research indicates that second-generation immigrants living in communities with high immigration concentrations tended to have lower levels of crime than those living in communities with low concentrations of immigrants. Crime rates among the second generation were also higher in areas with higher levels of poverty and unemployment. However, among white and Asian American adolescents, substance use increased in the second and third generations, but there was little change for violent and property delinquency across generations. On the other hand, among black adolescents, violent and property delinquency increased in the second and third generations, but substance use remained the same across three generations.

The overall high level of criminality among the second generation appears to be consistent with self-selection theory. The children of immigrants are not self-selected, and many are unable to overcome the challenges they encounter in their new homeland, including the lack of education and economic opportunities as well as culture conflicts, alienation, and exposure to deviant subculture. On the other hand, variations in the changing patterns of delinquency across locations and generations for different racial groups suggest the effects of acculturation and segmented assimilation on crime and delinquency. Increased levels of substance use among second-generation Asian and white youth suggest the result of acculturation and the integration of these youth into the mainstream society and the American middle class. Alcohol, which technically is a drug, has become a part of American culture, and moderate drinking is positively associated with incomes and education, which are higher among non-Hispanic whites and Asians than among blacks and Hispanics. On the contrary, the pattern of increasing violent and property delinquency among blacks and Hispanics in the second and third generations reflects the assimilation and integration of these youth into the adversarial subculture of disorganized and

deprived neighborhoods. Blacks and Hispanics experience higher levels of poverty and residential segregation than their white and Asian counterparts. As the protective effects of traditional families, ethnic cultures, and ethnic identity diminish in the second and later generations, living in the slum facilitates the assimilation of second-generation black and Hispanic youth into the neighborhoods' deviant subculture and increases their involvement in property and violent delinquency.

Crime Among Non-Citizens

The term *non-citizens* used in crime reports compiled by the U.S. Bureau of Justice Statistics refers to permanent residents, alien immigrants who are not naturalized or who do not have permanent resident status, foreign nationals who are in the country temporarily, and illegal immigrants (or undocumented immigrants). Crime committed by alien immigrants was included for the first time in the report titled "Report on Crime and the Foreign-Born," issued by the National Commission on Law Observance and Enforcement (1931). Although not all alien immigrants entered the United States illegally, they were considered a different group from immigrants who had the legal status of permanent residents. The report indicated a considerable number of homicides (12%–25% of all offenses) committed by alien immigrants incarcerated in U.S. penal institutions. Although it was not possible for the investigation to compare homicide rates among aliens, naturalized immigrants, and native-born groups, the commission was concerned with the fact that a large proportion of incarcerated alien immigrants committed these serious crimes shortly after their arrival in the United States.

In recent years, confusions between legal immigrants and illegal immigrants often exist in debates about immigration and crime. There has been a tendency to lump these two groups into the general term *immigrants*. When illegal immigrants are distinguished from legal immigrants, the first group is often thought of being responsible for a large proportion of criminal behaviors committed in the United States. It has been argued that because of the risk of deportation, illegal immigrants are afraid to report crimes committed against them to the police, making official estimates of crime in the illegal immigrant community artificially low. No evidence exists, however, that reporting biases seriously affect estimates of the homicide victimization rates because, unlike other crimes, homicide cases need to have a body. In fact, at the national level, the homicides committed by illegal immigrants in the United States are reflected in the data just like homicides in other social groups. The view that illegal immigrants disproportionately engage in serious criminal behavior is not consistent with the fact that from 1994 to 2001, violent crime rates in the United States declined 34.2% and property crime declined 26.4%, while in the same period of time, the illegal immigrant population doubled to 12 million.

Available statistics from the Department of Justice indicate that the number of non-citizens in the federal criminal justice system increased for the period of 10 years from 1994 to 2003, but most non-citizens in federal prisons were foreign nationals who had been in the country temporarily. These non-citizen offenders were overwhelmingly charged with immigration offenses, including unlawful entry and reentry as well as smuggling, transporting, or harboring unlawful aliens. A smaller proportion of non-citizen offenders were charged with drug-related offenses. Because of their short period of time in the United States, they were less likely than their U.S.-citizen counterparts to have a known criminal history. Non-citizens have also been found to disproportionately engage in organized crime. According to Perry (2000), new immigrants from Latin America, Africa, Asia, and eastern Europe, particularly Russia, are all represented in organized-crime groups, but a substantial proportion of organized crime groups include foreign nationals who came to the United States with the explicit intent of expanding the domain and market of the organizations that already exist in their home countries. Asian syndicates tend to control much of the drug smuggling, prostitution, and other vice markets on the West Coast as well as parts of New York and New Jersey. Caribbean cartels dominate the drug trade in the southeast United States. Fraud, extortion, and burglary by Russian mafia are less localized but spread across the nation. Nigerians, operating in small cells, engage in some heroin smuggling, but they are more commonly specialized in massive fraud schemes. These criminal groups are able to exploit their bonds with current immigrants on the basis of their common place of origin as well as their cultural and social desire to reproduce the structures of hierarchy, complicity, and conspiracy of silence similar to those in their homelands.

Victimization Experienced by Immigrants

Crime committed by immigrants has been a topic for research for more than a century, but little attention has been paid to victimization experienced by immigrants. In recent years, research has begun to explore the extent and nature of crime against immigrants. Overall, immigrants tend to have a higher level of victimization and fear of crime as compared with the native-born, but there are differences across types of victimization.

Property Crime Victimization

Limited research suggests that immigrants do not experience higher property victimization rates than native-born individuals, except theft. Factors related to the risk of victimization, including being young and single, living in public housing, and living in an urbanized environment, are the same for immigrants and native-born persons. There is speculation, however, that the rates of property victimization

experienced by immigrants may be much higher than what has been reported and that many crimes against immigrants go unreported because they are reluctant to come forward. Another reason is that many new immigrants are poor and live in high-crime neighborhoods, and they do not understand the environment risks in the United States.

Violent Crime Victimization

Most studies on victimization among immigrants have tended to focus on homicide. These studies have found that immigrants were at higher risk of becoming a homicide victim than native-born people. According to Martinez and Lee (2000), the rate of homicide victimization among the foreign-born was 23 per 100,000, compared with 18 per 100,000 among the native-born. Foreign-born Mariel Cubans in Miami experience a homicide victimization rate that exceeds the average city rate, but their homicide victimization rate was still lower than that among African Americans. Studies conducted by Sorenson and Shen (1996) and Sorenson and Lew (2000) have revealed similar findings. Immigrants in California were overrepresented in homicide victimization statistics. In 1990, immigrants constituted 23% of California's residents and 33% of California's homicide victims. There were variations across ethnic-racial groups, however. Among non-Hispanic whites, Hispanics, and blacks, immigrants had higher homicide rates than their native-born counterparts, but foreign-born Asians and native-born Asians had similar rates. In addition, patterns of victim-offender relationships in homicide victimizations among immigrants and natives also differed. Homicides by non-strangers were more common among the native-born than among the foreign-born, and the suspects of homicides against native-born victims were much more likely to be native-born, but suspects of immigrant homicides were more likely to be unknown. When the suspects were known, offenders of homicide against the foreign-born tended to also be foreign-born.

Victimization Among Undocumented Immigrants

Undocumented immigrants are at a heightened risk of victimization and have few outlets for dealing with crime. Violent acts against undocumented immigrants range from drive-by shootings to assaults and thefts. Among undocumented immigrants, day laborers, who search for work on a daily basis in a public and visible spaces, such as a busy street, sidewalk, storefront, or empty parking lot, encounter violence primarily from other day laborers; police; their employers; and, to a lesser extent, merchants and local residents. According to Valenzuela (2006), day laborers are particularly vulnerable to theft because most of them do not have bank accounts where they can deposit their earnings. Opening a bank account usually requires the provision

of an individual taxpayer identification number, which most day laborers do not possess. As a result, they are usually paid in cash for their work. The fact that they often keep cash on their person, combined with their reluctance to call the police, which is often due to their unfamiliarity with U.S. institutions and their lack of legal documents, makes them an easy target. Day laborers are also exposed to violence at hiring sites that are controversial or particularly volatile as a result of community conflicts. Limited data on anti-immigrant violence indicate that the intensity and frequency of immigrant bashing vary across regions. Perry (2000) indicated that anti-immigrant violence tends to be most prevalent in areas with disproportionate shares of newly arrived immigrants, such as New York, New Jersey, Arizona, California, and Texas. In particular, in California, Arizona, and Texas both legal and illegal immigrants experience border violence, ranging from verbal taunts to rock throwing and shots fired by vigilantes and border patrol agents

Conclusion

Evidence from early and recent studies does not warrant an assertion about the causal effect of immigration on crime, or excessive criminality among any particular national group. Instead, research findings indicate a limited role of immigration in causing the crime problem. Immigrants are considered self-selected individuals who have low levels of criminal propensity; but high rates of arrest, conviction, and imprisonment among certain immigrant groups in certain locations and times are attributed to the large proportion of young males in these immigrant groups, culture conflicts, adverse social and economic conditions of resettlement locations, and negative effects of acculturation and assimilation. Thus, immigration resettlement programs that provide support to new immigrants to ease the process of acculturation, retain positive aspects of immigrants' traditional cultures, and facilitate the integration of immigrants to the mainstream society can reduce crime and delinquency among young immigrants and members of the second generation. Limited research also shows no evidence that illegal immigrants disproportionately contribute to the crime problem in the United States. Most of the non-citizen offenders committed immigration offenses, and only a small proportion of them have crossed the U.S. border without permission. On the other hand, immigrants, especially illegal immigrants, have a higher risk of victimization and fear of crime but less recourse for the problem than do native-born individuals. An illegal status in particular contributes to the risk of victimization among undocumented immigrants. Because most of the studies on victimization among immigrants tend to focus on homicide, and because crime victimization among illegal immigrants has not been thoroughly studied, more research is needed to provide additional understandings of the nature, extent, and social

contexts of victimization experienced by immigrants as well as crime and victimization among illegal immigrants.

PART III

THEORIES OF CRIME AND JUSTICE

BIOLOGICAL THEORY

ANGELA D. CREWS
Marshall University

Biological theories within the field of criminology attempt to explain behaviors contrary to societal expectations through examination of individual characteristics. These theories are categorized within a paradigm called *positivism* (also known as *determinism*), which asserts that behaviors, including law-violating behaviors, are determined by factors largely beyond individual control. Positivist theories contrast with *classical theories*, which argue that people generally choose their behaviors in rational processes of logical decision making, and with *critical theories*, which critique lawmaking, social stratification, and the unequal distribution of power and wealth.

Positivist theories are further classified on the basis of the types of external influences they identify as potentially determinative of individual behavior. For example, psychological and psychiatric theories look at an individual's mental development and functioning; sociological theories evaluate the impact of social structure on individuals (e.g., social disorganization, anomie, subcultural theories, opportunity, strain) and the impact of social function and processes on individuals (e.g., differential association, social learning, social bonds, labeling). Biological theories can be classified into three types: (1) those that attempt to differentiate among individuals on the basis of certain innate (i.e., those with which you are born) outward physical traits or characteristics; (2) those that attempt to trace the source of differences to genetic or hereditary characteristics; and (3) those that attempt to distinguish among individuals on the basis of structural, functional, or chemical differences in the brain or body.

This chapter is organized in rough chronological order and by historical figures associated with an important development. It is difficult to provide an exact chronology, because several important developments and movements happened simultaneously in various parts of the world. For example, although biological theories are considered positivist, the concept of positivism did not evolve until after the evolution of some early biological perspectives. In addition, biological theories of behavior that involve some aspect of evolution, genetics, or heredity are discussed in terms of those scientific developments, although physical trait theories still continued to be popular.

The following sections discuss some of the more important and relevant considerations in scientific developments that impacted biological theories of behavior. A brief history of positivism also is provided, tracing the development and use of the biological theories from early (largely discredited) beliefs, to the most current theories on the relationship of biology to behavior. This section also provides a conclusion that discusses the role of biological theories in the future of criminological thought.

Classical and Positivist Views of Behavior

Biological theories are a subtype of positivist theory. Positivism evolved as instrumental in explaining law-violating behaviors during the latter part of the 19th century as a response to the perceived harshness of classical school

philosophies. Classical thought, which emerged during the Age of Enlightenment (mid-1600s to late 1700s), asserted that man operated on the basis of free will and rational thought, choosing which courses of action to take. According to classical theorists, individuals would engage in behaviors that were pleasurable and avoid behaviors that were painful. Punishment (of the right type and in the right amounts) would deter an individual from committing an act if that punishment resulted in pain that outweighed the pleasure. Classical theorists, for the most part, denounced torture as a type of punishment because it was more punishment than was necessary to prevent a future occurrence of the act; they believed that punishment should be proportionate to the crime to be effective as a deterrent.

Classical views were not very concerned about the causes of behavior. Behaviors were seen as the result of choice rather than as the result of inherent or external factors largely uncontrollable by the individual. The significant progression of scientific thought and method, however, led to the application of science in the study of human and social behavior. The central focus of these new ideas was that the aim of any social action toward individuals who violated law should be curing them, not punishing them.

Positivist criminology is distinguished by three main elements: (1) the search for the causes of crime, whether biological, psychological, or sociological; (2) the use of the scientific method to test theories against observations of the world; and (3) the rejection of punishment as a response to law-violating or deviant behavior, replaced with treatment based on the medical (rehabilitation) model. Positivism rejects free will and replaces it with scientific determinism. Finally, it rejects focus on criminal law and replaces it with a study of the individual.

The Scientific Method

The scientific method is important to positivism and to biological theories of crime because it provides a systematic way to examine a particular problem or issue, rather than relying on spiritual or mystical explanations or haphazard guesswork. The development of the modern scientific method is credited primarily to Ibn al-Haytham (965–1039), an Iraqi-born scientist who wrote *The Book of Optics* between 1011 and 1021. It consists of the following seven steps:

1. Observation: Visual examination of a problem or issue, noticing characteristics and patterns.
2. Statement of the problem: A verbal description of the problem or issue, noting how it impacts and relates to other events or factors. An explanation of why and how the issue or problem is a problem.
3. Formulation of hypotheses: Development of potential explanations or solutions, educated and informed statements about the expected nature of the problem and relationships among the various components of the problem, specification of variables involved in the problem so that the potential explanation can be tested.
4. Testing of the hypotheses using controlled experimentation: controlled manipulation of the variables to determine whether the hypotheses are supported.
5. Analyses of experimental results; this usually involves examination of statistics.
6. Interpretation of data obtained from the testing and analyses and the formulation of a conclusion: Taking into account all the factors, the researcher makes a conclusion about the nature of the problem or issue.
7. Publication or dissemination of findings to inform interested populations and future research: providing information to the scientific community about your findings to help future researchers or to inform policy and practice.

Although some variation of the scientific method has been used since ancient times to evaluate and solve many problems, its use to explain social problems, such as crime and criminality, developed more recently. Early types of biological theories of crime were among the first efforts. Given the use of the scientific method in the “hard” or “natural” sciences, early researchers of the causes of crime attempted to explain criminal behaviors by applying the scientific method. The most obvious place to look for differences between criminals and other individuals was on the outside, by studying physical traits.

Physical Trait Theories

The belief that one can determine a person’s character, moral disposition, or behavior by observing his or her physical characteristics is ancient. Pythagoras, a philosopher, mathematician, and scientist who lived during the period around 500 BCE, may have been one of the first to advocate this practice, known as *physiognomy*.

Physiognomy

The term *physiognomy* comes from the Greek words *physis*, meaning “nature,” and *gnomon*, meaning “to judge or to interpret.” It refers to the evaluation of a person’s personality or character (i.e., his or her nature) through an examination of that person’s outward appearance. Early physiognomy concentrated on characteristics of the face through which to judge the person’s nature. Aristotle, a Greek philosopher who lived from 384 to 322 BCE, was a proponent of physiognomy, as were many other ancient Greeks. The practice flourished in many areas of the world and was taught in universities throughout England until it was banned by Henry VIII in 1531.

Giambattista della Porta (1535–1615)

The publication of *On Physiognomy* in 1586 by Italian scholar Giambattista della Porta once again brought renewed focus to this belief and practice of the ancient Greeks. Della Porta, often considered the first criminologist,

examined patients during his medical practice and concluded that appearance and character were related. He approached the study of this relationship from a magico-spiritualistic metaphysical perspective instead of a scientific one, classifying humans on the basis of their resemblance to animals. For example, men who look like donkeys are similar to donkeys in their laziness and stupidity; men who resemble pigs behave like pigs.

Johann Kaspar Lavater (1741–1801)

Della Porta's ideas were extremely influential to Johann Kaspar Lavater, a Swiss pastor who published his painstakingly detailed study of facial fragments in 1783. He concluded that one could determine criminal behavior through an examination of a person's eyes, ears, nose, chin, and facial shape.

Phrenology

Phrenology, from the Greek words *phren*, meaning "mind," and *logos*, meaning "knowledge," is based on the belief that human behavior originated in the brain. This was a major departure from earlier beliefs that focused on the four humors as the source of emotions and behaviors: (1) sanguine (blood), seated in the liver and associated with courage and love; (2) choleric (yellow bile), seated in the gall bladder and associated with anger and bad temper; (3) melancholic (black bile), seated in the spleen and associated with depression, sadness, and irritability; and (4) phlegmatic (phlegm), seated in the brain and lungs and associated with calmness and lack of excitability. Theoretically and practically relocating responsibility for behavior from various organs to the brain represented a major step in the development of the scientific study of behavior and in the development of biological explanations of crime and criminality.

Franz Joseph Gall (1758–1828)

Around 1800, Franz Joseph Gall, a German neuroanatomist and physiologist who pioneered study of the human brain as the source of mental faculties, developed the practice of *craniology*, a technique by which to infer behaviors and characteristics from external examination of the skull (cranium). According to Gall, a person's strengths, weaknesses, morals, proclivities, character, and personality could be determined by physical characteristics of his or her skull.

Gall mapped out the location of 27 "brain organs" on the human skull. A bump or depression in a particular area of the skull would indicate a strength or weakness in that particular area. For example, several areas of Gall's map of the skull were believed to correspond to that person's tendencies to engage in criminal or deviant acts. One area corresponded to the tendency to commit murder; another area corresponded to the tendency to steal. Although not widely

accepted in Europe, the English elite (and others) used Gall's ideas to justify the oppression of individuals whose skulls had bumps or depressions in the wrong areas. The practice also was widely accepted in America between 1820 and 1850. Although crude, and somewhat ridiculous by today's standards, Gall's efforts had significant impact on subsequent research that attempted to identify the brain as the origin of behavior. Although similar to physiognomy in that it tried to make inferences about character and behavior from outward characteristics, craniology attempted to correlate those outward physical characteristics to internal physical characteristics (i.e., brain shape), which was a significant advance.

Johann Spurzheim (1776–1832)

Spurzheim, a German physician and student of Gall's, actually coined the term *phrenology* to replace *craniology*. Spurzheim also expanded the map of the brain organs, developed a hierarchical system of the organs, and created a model "phrenology bust" that depicted the location of the brain organs.

While the German scientists were focusing attention on the brain as an important determinant of individual behavior, various other scholars were theorizing about the development of man as a biological organism; about the nature of social and political organizations; and about the place of man, as an individual, within those organizations. The synthesis of these ideas would significantly advance the progress of research related to biological perspectives of behavior.

The Origins of Humanity and the Mechanisms of Inheritance

Since the beginning of time, humans have questioned their origins. Earliest explanations focused on mystical/magical and spiritual forces, often centered on creationism, the theory that life originated from a divine source. The power of the organized religions in shaping man's social, political, economic, and legal systems is testament to their immense influence. For example, religious perspectives dominated philosophical thought until the Scientific Revolution began in the mid-16th century, when advances in theory and practice provided explanations alternative to those promulgated by the church. Galileo Galilei (1564–1642), Johannes Kepler (1571–1630), René Descartes (1596–1650), and Isaac Newton (1643–1727) all made significant contributions that brought scientific reasoning to the forefront of thought as a competitor to spiritual explanations. Although usurping the philosophies of the church were not their main goals, their revolutionary ideas (that natural events and human behaviors may be explained by the development and application of certain scientific principles) had just that effect. Needless to say, secular science was not very popular with the church and organized religion. However, these changes were vital in advancing understanding of human and societal behavior.

Persistence of Human Traits and Characteristics

In addition to having been the potential source of physiognomy, ancient Greek philosophers also were among the first to recognize and attempt to explain the persistence of traits and characteristics from one generation to the next. Plato and Aristotle used the concept of *association* to explain how current mental processes (especially memories) generate from prior mental processes. These beliefs broadened to include all mental processes in the hands of philosophers such as Hume, Mill, and Locke.

Given that memories and other, possibly undesirable, characteristics and traits could potentially persist through generations, Plato advocated the control of reproduction by the state (government). Infanticide was practiced as a form of population control in ancient Rome, Athens, and Sparta. Many of the ancient societies also engaged in practices to weed out weak, diseased, malformed, or otherwise unfit members, such as exposing young children to the elements to see which ones had the strength, intelligence, and wit to survive.

Scientists began studying the nature of persistent traits in plants and animals prior to the application of these ideals to humans. Once established, however, it took relatively little time and relatively little effort to explain human patterns with these principles. As readers will note, the mid- to late 18th century was characterized by rapid progress in the natural sciences, which positively impacted biologically oriented research in the social sciences.

Carolus (Carl) Linnaeus (1707–1778)

Linnaeus, a Swedish botanist, zoologist, and physician, was among the first to document traits, patterns, and characteristics among plants and animals, creating hierarchical taxonomies (systems of classification). In *Systema Naturae* (System of Nature), published in 1735, Linnaeus grouped humans with other primates, becoming one of the first to recognize similar characteristics across species, hinting at an evolutionary progression.

Pierre-Louis Moreau de Maupertuis (1698–1759)

In 1745, French philosopher and mathematician Maupertuis published *Venus Physique* (Physical Venus), in which he proposed a theory of reproduction in which organic materials contained mechanisms to naturally organize. He subsequently discussed his views on heredity and examined the contributions of both sexes to reproduction, examining variations through statistics. Whether Maupertuis can be credited with being among the first to attempt to elucidate a theory of evolution is actively debated. He is generally credited with outlining the basic principles of evolutionary thought, along with his contemporary, James Burnett (see *James Burnett, Lord Monboddo* [1714–1799] section).

David Hartley (1705–1757)
and the Associationist School

Hartley (borrowing somewhat from philosopher John Locke) published his most influential work—*Observations on Man, His Frame, His Duty, and His Expectations*—in 1749. In it, he attempted to explain memory and thought, in general, through the doctrine of association. This was significant, because he attempted to link the processes of the body to the processes of the brain. He explained that actions and thoughts that do not result immediately from an external stimulus are influenced by the constant activity of the brain because of man's past experiences, mediated by the current circumstances, causing man to act in one way or another. This brain activities that Hartley called *sensations* are often associated together and become associated with other ideas and sensations, forming new ideas. Hartley's work was important in that it brought scientific focus to the process of thought, the origin of emotions, and the impact of feelings on the creation of voluntary action. This is a positivist philosophy in that action is not viewed as being the direct result of strict free will.

George-Louis Leclerc,
Comte de Buffon (1707–1788)

From 1749 to 1778, Leclerc published his most famous and influential work in 36 volumes, with an additional 8 volumes published postmortem. It was a study of natural history, from the general to the specific. In this work, he proposed the idea that species, including humans, change (i.e., evolve) throughout generations. Following in the footsteps of Linnaeus, he also proposed the radical idea of a relationship between humans and apes.

In another controversial publication, *The Eras of Nature* (1778), Leclerc questioned the long-standing and sacred belief that the universe was created by a divine power, instead suggesting that our solar system was created by celestial collisions. Finally, he contradicted the notion that seemingly useless body parts on animals were spontaneously generated but instead were vestigial, remnants of evolutionary progress.

Leclerc's influence was widespread and impacted subsequent beliefs about the transmission of traits from one generation to the next (inheritance, heredity) as well as about changes that occur over time with each passing generation (evolution). These ideas significantly impacted biological theories of behavior. Charles Darwin, in fact, credited Leclerc with being the first modern author of the time to treat evolution as a scientific principle.

James Burnett, Lord Monboddo (1714–1799)

Burnett, a Scottish judge, is credited with being another of the first to promote evolutionary ideas, in particular, the idea of natural selection. In *The Origin and Progress of Language* (1773), Burnett analyzed the development of

language as an evolutionary process; he clearly was familiar with the ideas of natural selection, although he differed with Leclerc in his support of the notion that humans were related to apes.

Erasmus Darwin (1731–1802)

One individual who took Leclerc's ideas to heart was Erasmus Darwin, grandfather of Charles Darwin and Francis Galton (see subsequent sections on Charles Darwin and Galton). Darwin also integrated ideas from Linnaeus, translating Linnaeus's works from Latin to English and publishing his own book of poetry about plants, *The Botanic Garden* (1791). Between 1794 and 1796, Darwin published *Zönomia*, which discussed the concept of generation (reproduction) and used Hartley's theory of association (and possibly Linnaeus's taxonomies). Many scholars believe Darwin's propositions were the forerunners of a more well-defined theory of inheritance later argued by Jean-Baptiste Lamarck (see *Jean-Baptiste Lamarck [1744–1829]* section).

Thomas Robert Malthus (1766–1834)

In 1798, Malthus, an English demographer and political economist, published *An Essay on the Principle of Population*, in which he proposed that populations struggle for existence in competition over resources. His main premise was that increases in population result in increased competition for scarce resources, primarily food. As a society becomes overpopulated, those at the bottom of the socioeconomic strata suffer the most (and often die). He explained that some natural events and conditions serve to control population growth (e.g., war, disease, famine) and that moral restraint (e.g., abstinence, late marriage) could serve the same function.

Contrary to many economists of the time who believed that increasing fertility rates and populations would provide more workers and would increase the productivity of a society, Malthus argued that the provision of resources could often not keep pace with population growth and would result in more poverty among the lower classes. This depiction of a struggle for existence was applied by subsequent scientists to plants and animals and was instrumental to Charles Darwin (and others) in arguments about "natural selection" and "survival of the fittest" (a phrase coined by Herbert Spencer; see *Herbert Spencer [1820–1903]* section).

Jean-Baptiste Lamarck (1744–1829)

Lamarck was a French naturalist, mentored by Leclerc (see preceding section on Leclerc), who published *Recherches sur l'Organisation des Corps Vivans* (Research on the Organization of Living Things) in 1802. Lamarck was among the first to attempt to classify invertebrates and was among the first to use the term *biology*. He primarily

is known for promoting and advocating a theory of *soft inheritance*, or *inheritance of acquired characters*, in which characteristics developed during the lifetime of an organism (e.g., larger or stronger muscles) are passed along to subsequent generations, making them better suited for survival (or better adapted).

Lamarck is considered the first to articulate a coherent theory of evolution, although he believed that organisms came into being through spontaneous generation instead of sharing a common source. His theory was characterized by two main arguments: (1) that organisms progress from simpler to more complex through generations and (2) that organisms develop adaptations because of their environments or because of the necessity (or lack thereof) of particular characteristics (the use-it-or-lose-it aspect).

The Impact of Positivism

In the early 1800s, following the advancement of arguments, proposals, and theories related to the biological sciences, and during the discussions of Malthus's revolutionary "struggle for existence," groundbreaking ideas also were being propagated about the place and function of man within social groups. These developments were instrumental to the application of biological perspectives to human behavior within social groups.

Auguste Comte (1798–1857)

Known as the "Father of Sociology," Comte was a French scholar who published *Plan de Travaux Scientifiques Nécessaires Pour Réorganizer la Société* (Plan of Scientific Studies Necessary for the Reorganization of Society) in 1822. In this work, he argued for a universal *law of three phases*: (1) theological, (2) metaphysical, and (3) scientific, through which all societies have, or will, progress.

The theological stage is the most primitive stage, characterized by supernatural, religious, or animistic explanations for events, situations, and behaviors and a lack of interest in the origins of causes. The metaphysical stage is slightly more advanced and identifies abstract forces (fate, accident) as the origin of causes. The most advanced stage, the scientific stage, is what Comte called the *positive* stage. At this point, there is little concern for the origin of actions, but a focus on the outcomes, which man can control.

Positive stages are characterized by observation, experimentation, and logic and attempt to understand the relationships among components. Comte's positivism attempted to apply scientific principles (i.e., the scientific method) to the behavior of societies and to the behavior of groups within societies and emphasized the connectedness of all the elements involved in behavior. Positivism is one of the first theories of social evolution, attempting to explain how societies progress. Comte claimed that the only real knowledge is knowledge gained through actual sense experience (i.e., observation).

Comte's scientific stage also is exemplified by the use of quantitative, statistical procedures to make logical, rational decisions based on evidence. Statistical procedures had been used for some time in the hard sciences (e.g., math, physics), but a positivist perspective required that the use of such measurement techniques be applied to the social sciences, as well.

Statistics and the Social Sciences

Adolphe Quetelet (1796–1894)
and *Andre-Michel Guerry (1802–1866)*

Despite the overwhelming complexity of social phenomena, Quetelet and Guerry were convinced that it was possible to apply statistical techniques to the investigation of social behavior. Both men were primarily interested in unraveling the statistical laws underlying social problems such as crime and suicide. This idea was controversial at the time, because it contradicted prevailing belief in free will. Quetelet's most influential publication was *Sur L'Homme et le Développement de ses Facultés, ou Essai de Physique Sociale* (Treatise on Man; 1835), in which he described the "average" man, developed from the calculation of mean values to form a normal distribution. Quetelet called this process *social physics*, a term that Comte had earlier used. Quetelet's appropriation of the phrase *social physics* prompted Comte to adopt the term *sociology* instead.

Guerry is known for developing the idea of *moral statistics* in an 1829 one-page document containing three maps of France, shaded in terms of crimes against property, crimes against persons, and a proxy for education (school instruction). A subsequent publication, *Essay on Moral Statistics of France* (1833), expanded on this technique and developed shaded maps to evaluate crime and suicides by age, sex, region, and season. He found that these rates varied by region but remained remarkably stable across the other factors.

This preliminary work emphasized the possibility that social measurements could provide insight into the regularity of human actions, forming a basis for the development of social laws, similar to the physical laws that govern the behavior of other objects and events in nature. Quetelet and Guerry were instrumental in the development of sociology and criminology, illustrating the possibility of measuring, determining the nature of relationships, and identifying patterns and regularities in social situations.

Heredity and Evolution

As the search for explanations of individual and social behavior improved through the application of statistical methods and the positivist insistence that the only real knowledge was that obtained through systematic observation (i.e., the scientific method), beliefs about the nature and potential of man within society became more sophisticated

and grounded. Although Lamarck had earlier discussed the passage of certain acquired traits from generation to generation (soft inheritance), theorists in the mid-1800s benefited from Malthus's propositions about the progress of society and from increasingly sophisticated inquiries into the nature and source of biological and behavioral predispositions.

Herbert Spencer (1820–1903)

An early English social theorist and philosopher, Spencer articulated a theory of evolution in *Progress: Its Law and Cause* (1857), prior to the publication of Charles Darwin's *On the Origin of Species* in 1859. Spencer proposed that everything in the universe developed from a single source and progressed in complexity with the passing of time and generations, becoming differentiated yet being characterized by increasing integration of the differentiated parts. Spencer also coined the phrase *survival of the fittest*, in 1864, after reading Darwin's *On the Origin of Species*, and he applied the idea of natural selection to society.

Charles Darwin (1809–1882)

Although the preceding paragraphs illustrate the development of scientific thought on the concepts of heredity and evolution, most scholars primarily note the impact of Charles Darwin. Darwin described his theories in two main publications: (1) *On the Origin of Species by Means of Natural Selection, or the Preservation of Favored Races in the Struggle for Life* (1859) and (2) *The Descent of Man and Selection in Relation to Sex* (1871).

In *On the Origin of Species*, Darwin detailed the theory that organisms evolve over generations through a process of natural selection. Darwin reached his conclusions and supported his observations through evidence that he collected during a sea voyage on a boat, the *HMS Beagle*, during the 1830s.

The Descent of Man and Selection in Relation to Sex applied Darwin's theory to human evolution and described the theory of sexual selection. Although he had earlier hinted that natural selection and evolution could and should be applied to the development of man, others (Thomas Huxley in 1863, Alfred Wallace in 1864) had actually applied his theories to the human animal first.

Cesare Lombroso (1835–1909)

Among the first to apply Darwin's findings to criminal behavior and criminals, Lombroso was an Italian criminologist and founder of the Italian School of positivist criminology. Lombroso rejected the established Classical School, which held that crime was a characteristic trait of human nature. Instead, using concepts drawn from earlier perspectives, such as physiognomy, Lombroso argued, in essence, that criminality was inherited and that someone "born criminal" (this phrase was coined by his student,

Enrico Ferri) could be identified by physical defects, which confirmed a criminal as savage, or atavistic.

Lombroso published *Criminal Man* in 1876, helping to establish the newly forming Positive School of criminology. Inspired by Charles Darwin's evolutionary theory, he believed that criminals were not as evolved as people who did not commit crime and that crime is a result of biological differences between criminals and noncriminals.

A central focus of Lombroso's work is the concept of *atavism*. Atavism describes the reappearance in an organism of characteristics of some remote ancestor after several generations of absence. It often refers to one that exhibits atavism, that is, a throwback. It can also mean a reversion to an earlier behavior, outlook, or approach. Lombroso approached this concept believing that criminals were throwbacks on the evolutionary scale. He believed that modern criminals shared physical characteristics (*stigmata*) with primitive humans. In his later years, he eventually thought that social and environmental factors can contribute to criminality.

Lombroso reached his conclusions by studying the cadavers of executed criminals for physical indicators of atavism, developing a typological system (with four main criminal types) to categorize these individuals. Although his methods were flawed, and most of the traits he listed failed to distinguish criminals from matched samples of noncriminals, he was among the first to apply scientific principles to the collection of data and to use statistical techniques in his data analysis. In addition to examining the physical characteristics of the criminal, he also evaluated the conditions under which crime is committed. He also was among the first to study female criminality, speculating that females were more likely to be criminals "by passion."

Lombroso determined that serious offenders inherited their criminal traits and were "born criminals," atavistic throwbacks to earlier evolutionary ancestors. They had strong jaws, big teeth, bulging foreheads, and long arms. These types of offenders constituted about one third of all criminals. The remaining two thirds were "criminaloids" (minor offenders) who only occasionally commit crime.

Although primarily remembered for his claim that criminal behaviors were inherited, Lombroso also argued that environmental factors can play an important role in crime. He speculated that alcoholism, climate changes, and lack of education may contribute to criminality.

Lombroso's work started other researchers on the path to determine a hereditary source for criminal behavior. His student, Enrico Ferri (1856–1929), disagreed with Lombroso's focus on the physiological, preferring instead to examine the interactive effects of physical factors, individual factors, and social factors and to blame criminality on a lack of moral sensibility.

Another Italian contemporary, Raffaele Garofalo (1851–1934), developed a theory of *natural crime*, focusing on those acts that could be prevented or reduced by

punishment. Garofalo also suggested the elimination of individuals who posed a threat to society, to improve the quality of the society and ensure its survival. Like Ferri, he believed crime was more the result of a lack in moral sensibilities rather than a physiological problem.

Lombroso's conclusions were challenged and refuted by Charles Goring (1870–1919), who wrote *The English Convict* in 1913. In a carefully controlled statistical comparison of more than 3,000 criminals and noncriminals, Goring found no significant physical differences between the two populations except height and weight (criminals were slightly smaller). His findings essentially discredited Lombroso's idea of the born criminal, although research into the search for criminal types continued.

The Criminal Physique

Evaluations and categorizations of a person's body build or physique also became popular as researchers attempted to link crime with some outwardly observable differences. In 1925, Ernst Kretschmer (1888–1964), a German psychiatrist, published *Physique and Character*, in which he described three categories of body type (asthenic, athletic, pyknic) associated with three categories of behaviors (cyclothemic, schizothemic, and displastic). *Cyclothemes* were manic-depressive and typified by soft skin, a round shape, and little muscle development, and tended to commit the less serious offenses that were more intellectual in nature. *Schizothemes* were antisocial and apathetic, committing the more serious violent offenses, and were either asthenic (thin and tall) or athletic (wide and strong). *Displastics* could be any body type but were characterized by highly charged emotional states and unable to control their emotions. Kretschmer associated displastics with sexual offenses. Although Kretschmer attempted to develop a typology that associated behaviors with physique, he did not put much consideration into the complex nature of behavior and its interaction with the environment.

Among those who continued this search was a contemporary of Goring, Harvard anthropologist Ernest Hooten (1887–1954). Dissatisfied with Goring's findings, Hooten spent 12 years conducting research into the criminal nature of man to disprove Goring and to support Lombroso. His first influential publication, *Crime and the Man* (1939), documented his study of 14,000 prisoners and 3,000 non-prisoner controls in 10 states. Hooten was more rigorous than Goring in his methods, differentiating his subjects on the basis of types of crime and by geographic, ethnic, and racial backgrounds.

Hooten agreed with Lombroso's idea of a born criminal and argued that most crime was committed by individuals who were "biologically inferior," "organically inadapt-able," "mentally and physically stunted and warped," and "sociologically debased." He argued that the only way to solve crime was by eliminating people who were morally, mentally, or physically "unfit," or by segregating them in an environment apart from the rest of society.

As Hooten was conducting his research and developing his conclusions, the sociological world was developing an interest in the contribution of social factors and social environments to the development of criminal behavior. Sociological research out of the University of Chicago (i.e., the Chicago School) stressed the impact of the social environment rather than an individual's biology as crucial to the development of crime. Hooten was widely criticized because of his failure to consider social factors and his myopic focus on biological determinism.

Gregor Mendel (1822–1884)

While scholars debated Darwin's claims and investigated whether criminals were born and were atavistic throwbacks to earlier historical periods, a piece of research on heredity in plants that was largely overlooked at the time it was published in 1866 was being rediscovered. This work provided quantitative evidence that traits were passed on from one generation to the next (or inherited), making it one of the most critical pieces of research related to biological theories of crime.

Mendel, an Austrian scientist, is known as the "father of genetics" (Henig, 2000). Although Mendel's work was largely ignored until after 1900 (in part because of the popularity of Darwin's theories), application of his *laws of inheritance* to individual and social development resulted in significant advances in biological theories of behavior.

Mendel's experiments with plants (in particular, peas) and with animals (in particular, bees) provided scientific support to some of the propositions suggested by Darwin in 1868, although Mendel's research predates that of Darwin. Darwin theorized that *pangenesis* explained the persistence of traits from one generation to the next. He discussed transmission and development in his laws of inheritance, arguing that cells within bodies shed "gemules" that carried specific traits from the parent organism to the subsequent generation. Darwin insightfully proposed that a parent organism's gemules could transmit traits to the following generation even though those traits may not have been present in the parent and that those traits could develop at any later point.

Mendel, however, was the one who developed support for the theory of inheritance through his experiments with the cultivation and breeding of pea plants, and the scientific support for *dominant* and *recessive* characteristics, passed from one generation to the next. His work also led to focus on the study of traits at the cellular level (genotypes) instead of at the observable level (phenotypes).

The Implications of Heredity and Evolution: Eugenics and Social Darwinism

Francis Galton (1822–1911) and Eugenics

It was in the work of Galton, a cousin of Charles Darwin, that statistics, biology, and sociology reached a

harmonic state. Reading Darwin's theories about variations in the traits of domestic animals set Galton on a path to study variations in humans. In doing so, he developed measurement techniques and analytic techniques to help him make sense of what he was observing. He first was interested in whether human ability was hereditary, and he collected biographical information about numerous prominent men of the time to chart the families' abilities over several generations. He published his results in a book called *Hereditary Genius* (1869), in which he concluded that human ability was inherited. He followed this work with a survey of English scientists (1883) in which he attempted to determine whether their interest and abilities in science were the result of heredity (nature) or encouragement (nurture). Galton stimulated interest in the question of (and coined the phrase) *nature versus nurture*.

Although Galton's work at that point was useful and had resulted in the development of numerous measurement tools (e.g., the questionnaire; fingerprint analysis) and statistical concepts (standard deviation, correlation, regression), it was his work with twins that provided the impetus for future inquiries into the nature-versus-nurture debate. Galton surveyed sets of twins to determine whether twins who were identical exhibited differences if raised in different environments and whether twins who were fraternal exhibited similarities if raised in similar environments. This work was published as "The History of Twins as a Criterion of the Relative Powers of Nature and Nurture" in 1875.

In 1883, Galton developed the concept of *eugenics*, his most controversial and abused philosophy. Eugenics advocated the encouragement, through the distribution of incentives, of "able" couples to reproduce in an effort to improve human hereditary traits. Part of his proposals included manipulating social morals to encourage the reproduction of the "more fit" and discourage reproduction of the "less fit." Galton's proposals were to change social mores and values rather than forcibly manipulating reproduction or eliminating those who were considered less fit. He believed that, without encouragement, it was the natural state of man (and thus of society) to revert to mediocrity, a phrase that came to be clarified as "regression toward the mean," which he viewed as repressive of social and individual progress.

Prevailing thought at the time was receptive to such ideals, in the belief that these policies would reduce or eliminate poverty, disease, genetic deformities, illnesses, and crime. Eugenics was originally conceived as a concept of social responsibility to improve the lives of everyone in society by encouraging individuals to selectively breed good traits in and bad traits out, but many who followed would use Galton's philosophies toward less than desirable ends.

After Galton's efforts, others attempted to document that crime was a family trait. In 1877, Richard Dugdale (1841–1883) published *The Jukes: A Study in Crime, Pauperism, Disease and Heredity*, in which he traced the descendants of matriarch Ada Jukes and found that most of the Jukes

family members (although they were not all biologically related) were criminals, prostitutes, or welfare recipients. Another family study, published in 1912 by Henry H. Goddard (1866–1957), traced 1,000 descendants of a man named Martin Kallikak, comparing his descendants who were conceived within wedlock to a woman of “noble birth” to his descendants who came from the bloodline he conceived out of wedlock with another woman, one of ill repute. Goddard concluded (although he later retracted his conclusions) that the legitimate bloodline was “wholesome,” whereas the illegitimate bloodline was characterized by “feeble-mindedness.”

Social Darwinism

Developments that ensued after Galton’s propositions of eugenics, and after the rediscovery and replication of Mendel’s work on the heritability of traits, were crucial to the study of man’s behavior, its potential biological roots, and to the study of man’s role and obligation in society. Malthus’s struggle for existence, Comte’s sociology, Quetelet and Guerry’s social physics and moral statistics, and the work of scientists (most notably Darwin) on transmutation, natural selection, survival of the fittest, and evolution resulted in perfect conditions under which scientific principles and statistical analysis could be applied to the human condition and to human behavior. A compilation of these philosophies resulted in the theory of *social Darwinism*, originally applied to the structure and function of social processes and organizations (e.g., government), with the primary belief that competition drives all social progress and only the strongest survive.

Mendel’s contribution was critical to the ideas of social Darwinism, explaining how observable characteristics (phenotypes) were inheritable and how a trait may appear in one generation that had not appeared in many prior generations. These atavisms, or throwbacks to an earlier evolutionary period, could be physical (e.g., vestigial tails, useless appendages) or behavioral (e.g., violence). Social Darwinists became interested in the question of whether social development (progress, evolution) could be engineered or controlled through manipulation of these traits. Other scientists studying the more undesirable behaviors of man (e.g., crime) were interested in whether social problems could be controlled through this type of manipulation. Many, however, such as noted political economist William Graham Sumner (1840–1910), advocated a *laissez-faire* philosophy with respect to the survival and progress of societies, noting that problems like poverty are the natural result of inherent inequalities and that the process of natural selection and survival of the fittest would mean a natural reduction in the problems over time (without social engineering or interference; Hodgson, 2004). Viewing society through the lens of social Darwinism, however, inevitably led to viewing man through the lens of social Darwinism.

During the late 1800s and early 1900s, while Goring, Hooten, and others were debating the role of biology in criminal behavior, others were quietly merging Malthus’s ideas on competition and survival among societies, Spencer’s insistence that individual evolution leads to social evolution, Mendel’s ideas on the heritability of traits, Darwin’s ideas on natural selection and evolution, and Galton’s ideas on eugenics into warped interpretations and applications of eugenics and social Darwinism.

The Legacy of Eugenics and Social Darwinism

With unprecedented immigration in the late 19th and early 20th centuries, American society struggled with increasing crime, poverty, suicide, and other social problems. Some, such as the theorists of the Chicago School, saw the solution in sociological explanations, whereas others turned to solutions implied in eugenics. Although a complete description of the misapplication of eugenics is beyond the scope of this chapter, it is important for the student of biological theories to understand the impact that eugenics had on the study of biological explanations of behavior.

In theory, eugenics argued for the improvement of human genetic qualities. Positive eugenics aims to increase the reproduction of desirable qualities, and negative eugenics aims to discourage the reproduction of undesirable qualities, to improve humanity and society. The underlying premise is that both positive and negative traits are inherited and passed down through generations. Early eugenicists focused on traits such as intelligence and on hereditary diseases or defects presumed to be genetic (Barrett & Kurzman, 2004). These eugenicists, following Galton’s philosophies, focused on societal changes (the provision of incentives) to encourage reproduction among those with positive traits and to discourage reproduction among those with negative traits.

In practice, however, and following a logical progression of thought, some believed eugenics to mean that persons with undesirable traits should be prevented from reproducing, or even be eliminated.

Although social Darwinists and eugenicists are alike in their goal to improve humanity and society through survival of the fittest, social Darwinists were more likely to assert that this improvement would take place in a natural process, with weak, diseased, undesirable, and unfit individuals being eventually weeded out. It is for this reason that social Darwinists opposed government intervention into problems such as poverty and crime, believing that natural forces would result in the reduction or elimination of these undesirable conditions. Eugenicists, on the other hand, encouraged active intervention.

It is this active intervention that became problematic, although it was not initially viewed as such. Activists promoted the use of contraception to prevent unwanted pregnancies, and state laws were written regulating marriages. Individuals who had ailments thought to be genetic were

prohibited from marrying and forcibly sterilized. This included individuals deemed to be “feeble-minded” or mentally ill.

The popularity of eugenics spread throughout the United States during the late 1800s and early 1900s. Charles Davenport (1866–1944), an influential American biologist, directed the Cold Spring Harbor Laboratory in 1910 and founded the Eugenics Record Office, hiring Harry H. Laughlin (1880–1943) as superintendent (Kevles, 1985).

Between 1907 and 1914, several states had passed sterilization laws. Laughlin, however, perceived these as ineffective and full of holes, prompting him in 1922 to draft a “model” law that was passed by 18 additional states (Lombardo, n.d.). In this model law Laughlin defined the populations that would be targeted by forced sterilization, including criminals, the very poor, epileptics, alcoholics, the blind, the deaf, the insane, and those who had a physical deformity. These practices were upheld as constitutional by the U.S. Supreme Court in 1927 in the case of *Buck v. Bell* and continued until 1981. More than 64,000 individuals in 33 states were forcibly sterilized under these laws.

With increased immigration came increased concerns about the quality and purity of the races. Responding to these concerns, Madison Grant (1865–1937), an American lawyer, wrote one of the first and most influential books about racial integrity, *The Passing of the Great Race* (1916). Grant wrote that the Nordic (i.e., white) racial line was the pinnacle of civilization. He warned against miscegenation (race mixing) and supported legislation against it. He argued for racial hygiene because the Nordic race was superior to any other, and any mixing would taint Nordic bloodlines, making them impure. He also warned that “undesirables” breed in greater numbers and would overrun the superior Nordic population if not controlled. He advocated the eradication of “undesirables” from the human gene pool coupled with the promulgation of more desirable and worthy racial types.

Grant’s work was immensely popular and was instrumental in the drafting and passage of the Immigration Act of 1924, which restricted the numbers of immigrants from the less desirable regions, such as southern and eastern Europe. His book also was translated into several languages. In 1925, it was translated into German, in which *Nordic* was replaced by the word *Aryan*. Adolph Hitler, who read the book shortly after its translation into German, would later call Grant’s work his “bible.”

In 1928, with sterilization laws and immigration restrictions in full swing, E. S. Gosney (1855–1942) founded the Human Betterment Foundation, an entity whose primary purpose was to compile and distribute propaganda about compulsory sterilization. Gosney hired Paul E. Popenoe (1888–1979) to assist him in the study of the impact of these sterilization laws in California. Their collaboration resulted in the publication of *Sterilization for Human Betterment: A Summary of Results of 6,000 Operations in*

California, 1909–1929 (Gosney & Popenoe, 1929), used by Nazi Germany to support its 1934 Law for the Prevention of Hereditarily Diseased Offspring. Furthermore, these arguments were used to justify policies of racial hygiene and racial cleaning that Nazi Germany enacted against Jews and other “undesirable” or “unfit” persons who did not meet the model of the Aryan ideal. The Nuremberg Laws enacted in 1935 consisted of the Law for the Protection of German Blood and German Honor, and the Reich Citizenship Laws, which prohibited the mixing of Germans with Jews (which really meant anyone not deemed to be German) and stripped so-called undesirables of their citizenship.

Although population control policies based on eugenics enjoyed widespread support in many countries prior to World War II, Nazi use of its philosophies to justify the eradication of approximately 6 million Jews and an additional 3 to 5 million others brought an immediate halt to its proliferation. However, sterilizations, marriage restrictions based on fitness, and prohibitions of racial intermarriage continued for decades. Marriage counseling, ironically developed by Paul Popenoe as a eugenic tactic to ensure marriage between fit individuals, also became a viable area of practice.

Despite the fact that the word *eugenics* is usually avoided, modern efforts to improve humanity’s gene pool persist. The Human Genome Project is one notable scientific effort to understand the genetic makeup and properties of human beings with an eye toward eradicating or preventing inheritable diseases and defects. Advances in science and the development of ethical guidelines provide hope that struggles to better understand the transmission and development of human traits and characteristics are not yet abandoned. This is especially important to the future of biological theories of criminality.

Post–World War II Research on Biology and Behavior

Body Physique and Crime

After World War II, research into the biological roots of crime persisted. Following in the footsteps of Lombroso in 1876, Kretschmer in 1925, and Hooten in 1939, William H. Sheldon (1898–1977) attempted to document a direct link between biology (specifically, physique) and personality (specifically, crime) through the development of a classification system of personality patterns and corresponding physical builds (Sheldon, 1940).

Running contrary to prevailing sociological emphases on the environmental correlates of crime, Sheldon chose to instead employ beliefs about Darwin’s survival of the fittest, Lombroso’s criminal man, and Galton’s eugenics. Sheldon argued for an “ideal” type, in which perfectly formed physique joined perfectly formed temperament and disposition. Any combination that deviated from this ideal

was associated with disorders of both personality and behavior. He claimed a physical basis for all variations in personality and body build.

During the 1940s, Sheldon developed and tested his classification system, known as *somatotyping*. He created three classifications: (1) *ectomorphs*, who were thin, delicate, flat, and linear; (2) *endomorphs*, who were heavy or obese, with a round, soft shape; and (3) *mesomorphs*, who were rectangular, muscular, and sturdy.

In subsequent studies of juvenile delinquency, Sheldon argued that mesomorphic types were more likely to engage in crime, ectomorphs were more likely to commit suicide, and endomorphs were more likely to be mentally ill. Although Sheldon linked physical and psychological characteristics and concluded that both were the result of heredity, he failed to support that conclusion with valid statistical methods.

Also during the late 1940s and early 1950s, Sheldon Glueck and Eleanor Glueck conducted longitudinal research into juvenile delinquency using control groups and added to Sheldon's list of somatotypes. They suggested the addition of a fourth type they called *balanced*. In their research, they found support for Sheldon's proposition that mesomorphs are more likely to commit crime. Among the juveniles they studied, the mesomorphic somatotype was disproportionately represented among delinquents by a ratio of nearly two to one as compared with nondelinquent controls. In addition, whereas only about 14% of delinquents could be classified as ectomorphs, nearly 40% of the nondelinquent controls could be placed in this category. Instead of concluding that body type led to delinquency, the Gluecks (1956) concluded that participation in delinquency (for which individuals are more likely to get arrested) may be facilitated by having a mesomorphic body type rather than an ectomorphic, endomorphic, or balanced body type.

Biological explanations for behavior lost much of their popularity during the 1960s with the belief that their inherent implication of inferiority often was misused to justify prejudice and discrimination. In addition, the 1950s and 1960s brought significant advances in the natural sciences and in the social and behavioral sciences. Once again, criminologists and other scientists turned to evaluating the internal components and processes of the human body.

Genetics in Modern Biological Theories

Efforts to find a genetic explanation for violence and aggression have been met with strong resistance, primarily because of painful memories of how research linking biology and crime were used in the past (eugenics). In 1992, a conference related to the Human Genome Project at the University of Maryland had its federal funding withdrawn for attempting to discuss any particular linkage between genes and violence (Murphy & Lappé, 1994). Objections by groups who believed that any such research would be

used to oppress poor and minority populations overpowered the quest for knowledge.

Although genetic research began with Mendel's laws of inheritance, our understanding of how genes influence our behaviors is still evolving. Discovery of the genetic code in the mid-1950s took us beyond recognizing that genes were involved in heredity to a greater understanding of the process through which hereditary traits are passed from one generation to another. Part of this discovery process was the clarification of the structure and function of chromosomes, which carry human genetic material.

Chromosomes

Human cells normally have 22 pairs of chromosomes, plus a pair of chromosomes that determines sex, for a total of 46. Sex chromosomes are termed *X* and *Y*. Females carry a combination of *XX*, and males carry a combination of *XY*. During conception, the male's sperm carries genetic material to the female's egg. If the sperm that fertilizes a female egg is carrying a *Y* chromosome, the resulting embryo will develop into a male fetus (*XY*). If the sperm is carrying an *X* chromosome, the resulting embryo will develop into a female fetus (*XX*).

During this process, however, things can develop abnormally. For example, during the process, some men are left with an extra *Y* chromosome (*XYY*). Erroneously termed *XYY syndrome*, a "supermale" carrying this chromosomal pattern usually has a normal appearance and will probably never know that he carries an extra *Y* chromosome, unless he is genetically tested for some other reason. Given the *Y* chromosome's association with the male sex and with increased production in testosterone, many claims have been made in the research literature that *XYY* males are more aggressive and more violent. This supposition has not been supported with scientifically valid research.

Scientific progress made inquiry into genetic correlates of behavior more precise and less speculative. Although scholars are reluctant to associate criminal behavior with any specific gene, researchers continue to investigate the inheritability of behavioral traits. Some of the most promising work involves the study of twins and adoptees.

Twin Studies

Since Galton's work with twins, twin studies have become more sophisticated and have attempted to respond to methodological criticisms. Distinctions between fraternal (dizygotic [*DZ*]) and identical (monozygotic [*MZ*]) twins have contributed to the sophistication of this type of research. *DZ* twins develop from two eggs and share about half of their genetic material, whereas *MZ* twins develop from a single egg and share all of their genetic material.

Twin studies attempt to control for the impact of the social environment, hypothesizing that these environments are similar for twins. Twins generally are raised in the same

social environment, so the impact of the social environment is considered to be equal and consistent (and thus controlled). Therefore, any greater similarity between identical twins than between fraternal twins would provide evidence for a genetic link.

One of the earlier and simpler twin studies was conducted in the 1920s by Johannes Lange (1929). He studied 30 pairs of twins who were of the same sex. Seventeen of these pairs were DZ twins, and 13 of these pairs were MZ twins. At least one of each twin pair was known to have committed a crime. However, Lange found that both twins in 10 of the 13 MZ twin pairs were known criminals, compared with both twins in only 2 of the 17 DZ pairs.

More sophisticated and extensive studies have followed. In 1974, Karl O. Christiansen evaluated the criminal behavior of 3,586 twin pairs born in Denmark between 1881 and 1910. He found that the chance of one twin engaging in criminal behavior when the other twin was criminal was 50% among the MZ twin pairs but only 20% among the DZ twin pairs. The correlation between the genetic closeness of the biological relationship and crime was especially true for serious violent crime and for more lengthy criminal careers.

These findings were supported by additional work on the self-reported delinquency of twins in the 1980s and 1990s by David C. Rowe and his colleagues. This research found that MZ twins were more likely than DZ twins to both be involved in delinquent activity. Moreover, MZ twins reported more delinquent peers than did DZ twins (Rowe, 1983). The work of Rowe and his colleagues supported a genetic component to delinquency but also provided evidence of a social component.

Although twin studies have provided some support for a genetic component to behavior, it is difficult to separate the influence of genetics from the influence of social factors. There also are theoretical problems with the assumption that twins raised in the same home are subject to the same treatment and the same social environment. Even scholars who study the link between criminal behavior and genetics are cautious with their conclusions, arguing that these types of studies reveal only that the similarities between twins have some impact on behavior. Whether these similarities are genetic, social, or some combination of the two is still open for debate. Studies of adopted individuals constitute one attempt to resolve this issue.

Adoption Studies

In adoption studies, the behavior of adoptees is compared with the outcomes of their adopted and biological parents. The aim is to separate out the impact of the environment from the influence of heredity. This research asks whether a child will exhibit traits of the adopted parents or of the biological parents.

Research indicates that an adoptee with a biological parent who is criminal is more likely to engage in property

crime than other adoptees and that this effect is stronger for boys. The findings, from a study of 14,427 Danish children adopted between 1924 and 1947, provide evidence that there may be a genetic factor in the predisposition to antisocial behavior (Mednick, Gabrielli, & Hutchins, 1984). Studies in both Sweden and in the United States confirm these conclusions.

A meta-analysis of adoption studies, conducted by Walters and White (1989), reinforced the importance of adoption studies as the best way to determine the impact of both environment and genetics on criminal behavior but also emphasized the theoretical and methodological difficulties inherent to this approach. Knowing, for example, whether an adoptive parent has a criminal history provides no information on the social environment provided in the adoptive parent's home. The definitions of crime and criminality also widely vary in these studies and can be challenged. For example, one study may consider as criminal behaviors perhaps best classified as antisocial (e.g., using bad language, adultery). Furthermore, these studies do not account for the quantity or quality of social interactions experienced within the various settings (adoptive vs. biological). Finally, the determination that someone is a criminal simply on the basis of a conviction or incarceration is problematic and does not consider undetected criminal behaviors.

According to researchers who worked on the Human Genome Project, however, twin and adoption studies are the best source for evaluating individual differences in human behavior. Recent studies have consistently demonstrated that genetic variation substantially contributes to behavioral variation across all types of behavior. Two primary conclusions are derived from these studies: (1) Nearly all of the most frequently studied behaviors, characteristics, and conditions (e.g., cognitive abilities, personality, aggressive behavior) are moderately to highly heritable, and (2) nonshared environments play a more important role than shared environments and tend to make people different from, instead of similar to, their relatives.

Most biological scholars now cautiously conclude that there may be a genetic predisposition toward criminal behavior but that the manifestation of these predispositions is dependent on social and environmental factors. However, belief (or not) in a genetic link to criminality does not preclude other potential biological explanations of crime.

Biochemical Explanations: Hormones, Neurotransmitters, Diet

Another biological explanation for criminal behavior involves the body's hormones, released by some of the body's cells or organs to regulate activity in other cells or organs. *Androgens* are hormones associated with masculine traits, and *estrogens* are associated with feminine traits. *Progesterone* is another hormone associated primarily with female reproductive processes, such as pregnancy and menstruation.

Testosterone

Testosterone is considered the male sex hormone. Although persons of both sexes secrete testosterone, males secrete it in higher levels. Researchers have found that higher levels of this hormone are associated with increased levels of violence and aggression, both in males and females. Criminal samples have been found to have higher testosterone levels when compared with noncriminal samples, although these levels were still within normal limits.

Problems with attempting to explain criminal behavior by testosterone levels, however, are problematic. Testosterone levels naturally fluctuate throughout the day and in response to various environmental stimuli. For example, levels among athletes increase prior to competitions, perhaps indicating that testosterone is produced to increase aggression instead of as a response to aggression. This makes correlating levels to behavior and controlling for environmental stimuli extremely difficult.

Recent research conducted by Ellis in 2003, however, has added an evolutionary component. In his *evolutionary neuroandrogenic theory*, Ellis argued that increased levels of testosterone reduce the brain's sensitivity to environmental stimuli, making a person act out, with reduced abilities to control emotions. He also speculated that the development of testosterone's "competitive-victimizing" effects is the result of natural selection, as described by Darwin.

Scholars who study the relationship between testosterone levels and crime cite as support the differences between males and females in terms of levels of crime in general and levels of violence in particular. This work has led to the "treatment" of male sex offenders with chemical derivatives from progesterone to reduce male sexual urges through the introduction of female hormones (e.g., Depo-Provera, a brand of birth control for women). This has been effective in reducing some types of sex offenses (e.g., pedophilia, exhibitionism), but it has had little or no impact on other crimes or violence.

Premenstrual Syndrome and Premenstrual Dysphoric Disorder

Researchers also have investigated the impact of female hormones on behavior in women, beginning with two English cases in 1980 in which two women used *premenstrual syndrome* (PMS) as a mitigating factor in violent offenses. These efforts led to female defendants in the United States being able to argue reduced culpability due to PMS.

More recently, a more severe form of PMS has been identified. *Premenstrual dysphoric disorder* (PMDD) is a severe and debilitating form of PMS, distinguished by the level of interference the menstrual process has on the ability of the woman to engage in the functions of everyday life. Interestingly, researchers have established a genetic link to the development of PMDD. Women with a certain genetic structure have increased (abnormal) sensitivity to their own normal hormones, resulting in increased symptoms of emotional and physical stress.

Another phenomenon associated with female hormones is *postpartum depression syndrome*. Although most new mothers experience symptoms of depression in the weeks or months following birth, which is primarily thought to be due to a decrease in progesterone, approximately 1% to 2% of these mothers exhibit severe symptoms, such as hallucinations, suicidal or homicidal thoughts, mental confusion, and panic attacks. As with PMS and PMDD, postpartum depression syndrome has successfully been used as a mitigating factor in the legal defense of women accused of crimes while suffering from its effects. Both PMS and PMDD, however, are controversial concepts, difficult to diagnose as medical conditions, and argued by some to be social constructions and psychiatric problems instead of medical conditions.

Neurotransmitters

In addition to the possibility that human hormones may directly impact behavior, they also may directly impact chemicals that regulate brain activity. *Neurotransmitters* are chemicals that transmit messages between brain cells, called *neurons*, and have a direct impact on the many functions of the brain, including those that affect emotions, learning, mood, and behavior. Although researchers have extensively studied more than 50 of these chemicals, research on the biological bases of crime has focused on three of these: (1) *norepinephrine*, which is associated with the body's fight-or-flight response; (2) *dopamine*, which plays a role in thinking and learning, motivation, sleep, attention, and feelings of pleasure and reward; and (3) *serotonin*, which impacts many functions, such as sleep, sex drive, anger, aggression, appetite, and metabolism.

High levels of norepinephrine, low levels of dopamine, and low levels of serotonin have been associated with aggression. Results from research that has examined the impact of these neurotransmitters are mixed. With all of these chemicals, fluctuations in their levels may result in certain behaviors, and certain behaviors may contribute to fluctuations in their levels (in a reciprocal interaction effect).

Although there is little doubt that there is a direct relationship between levels of various neurotransmitters and behavior, this relationship is extremely complex and nearly impossible to disaggregate. Chemical changes are part of the body's response to environmental conditions (e.g., threats) and to internal processes (e.g., fear, anxiety), and environmental conditions and internal processes produce chemical changes in the body. This creates a chicken-and-egg question about whether our responses and reactions are the result of changes in our chemistry or changes in our chemistry are the result of our responses and reactions.

Diet, Food Allergies, Sensitivities, Vitamins, and Minerals

What one eats impacts one's body chemistry. High-protein foods, such as fish, eggs, meat, and many dairy

products, contain high levels of the amino acid *tryptophan*. Tryptophan produces serotonin (see preceding section). Another amino acid, *tyrosine* (also found in high-protein foods), is related to the production of both dopamine and norepinephrine. These relationships have suggested that many aggressive behaviors may be controlled with a diet higher in protein and lower in refined carbohydrates.

Carbohydrates—specifically, refined carbohydrates, such as white refined flour, white rice, white refined sugar, and any processed foods with high levels of sugar—also are examined as related to problem behavior. Complex carbohydrates are slowly transformed into glucose, which stimulates the production of insulin in the pancreas, which in turn produces energy for the body. Simple or refined carbohydrates are not processed slowly and result in the rapid release of insulin into the bloodstream, causing a sharp decrease in blood sugar, depriving the brain of the glucose necessary for proper functioning. This sharp decline in blood sugar also triggers the release of hormones such as adrenalin and increases in dopamine. This combination has been associated with increased aggression, irritability, and anxiety.

The state of having chronically reduced blood sugar caused by the excessive production of insulin is called *hypoglycemia*. Individuals who are hypoglycemic experience increased levels of irritability, aggression, and difficulty in controlling their emotional expressions. Hypoglycemia has successfully been used to mitigate criminal behavior. The most infamous example occurred during the late 1970s when Dan White killed San Francisco Mayor George Moscone and City Supervisor Harvey Milk after consuming nothing but junk food such as Twinkies and soda for several days. At trial, White's attorney successfully argued that White suffered from "diminished capacity" due to his hypoglycemia. His argument has come to be known as the "Twinkie Defense" (Lilly, Cullen, & Ball, 2007).

Experimentation with the diets of criminal populations have indicated that reducing intake of refined carbohydrates and increasing consumption of fruits and vegetables have significantly decreased behavioral problems and disciplinary write-ups. It is difficult, however, to separate the impact of diet from other potential factors that may affect behavior.

Other potential contributors related to food intake involve food allergies and the consumption (or not) of various vitamins and minerals. Once again, refined carbohydrates may be a culprit. These types of foods contain particularly high levels of cadmium and lead, two minerals known to cause damage to brain tissue and impact the production of neurotransmitters.

Several food components have been associated with reactions that may include aggressive, violent, or criminal behavior. Some people may be allergic to or exhibit increased sensitivity to chemicals contained in chocolate (phenylethylamine), aged cheeses and wine (tyramine), artificial sweeteners (aspartame), and caffeine (xanthines).

Others may react to food additives, such as monosodium glutamate and food dyes. Criminal populations also have been found to lack vitamins B3 and B6 in comparison to noncriminal populations.

Environmental Toxins

The frontal lobe of the brain, an area that has become the focus of biological investigations into criminal behavior, is particularly sensitive to environmental toxins, such as lead and manganese. Behavioral difficulties, such as hyperactivity, impulsivity, aggression, and lack of self-control, have been associated with increased levels of these heavy metals.

Examination of the impact of environmental toxins on human behavior is very promising because it integrates biological with sociological and criminological theories. Facilities that produce, store, treat, and dispose of hazardous wastes are largely to blame for the production of environmental toxins. Research has shown that proximity to these types of facilities increases the impairment of the brain and of the general central nervous system, producing lower IQs; reductions in learning abilities, frustration tolerance, and self-control; and increases in impulsivity, hyperactivity, antisocial behaviors, violence, and crime.

Researchers who study the relationship of environmental toxins to crime argue that our environment is producing crime by producing neurological damage. Scholars emphasize the fact that minority populations and lower-income groups are the ones most likely to live near these facilities and as a result are more likely than white and higher-income groups to be negatively impacted by these toxins. This, according to the researchers, may help explain why minorities and people from the lower classes seem to catch the attention of the criminal justice system in higher rates than others.

Brain Structure and Function

Whereas earlier biological theories considered the brain to be an organ with various areas of specialized function, modern theories recognize that the brain is a complex organism. Some areas of the brain are associated with specific functions (e.g., speech and vision), but all areas of the brain work together, and a problem or event in one area inevitably affects other areas. Although our understanding of the brain's structure and function has significantly advanced, we still know little about the relationship between the brain and many behaviors, such as those related to crime. In addition, we know little about how the environment affects the brain's structure and function.

The *frontal lobe* and the *temporal lobe* are two parts of the brain examined by researchers interested in criminal behavior. The frontal lobe is responsible for regulating and inhibiting behaviors, and the temporal lobe is responsible for emotionality, subjective consciousness, and responses to environmental stimuli.

Tools to evaluate brain structure, brain function, and behavior rely on sophisticated medical equipment and measurements, such as electroencephalography, computed tomography, magnetic resonance imaging, positron emission tomography, and single photon emission computed tomography. These devices have been used by researchers to compare the brain structures and brain functions between criminal and noncriminal populations. In addition to providing images of structure, many of these technologies can track real-time changes in the brain's neural activity before, during, and after exposure to physical or emotional stimuli.

Preliminary studies indicate that the brains of violent offenders and the brains of other individuals differ in both structure and function, but many of the studies have relied on very small sample sizes, which reduces the generalizability of these findings. Moreover, these studies also are plagued by questions of whether the brain causes the violence or whether violence results in changes to the brain. Evidence of structural or functional abnormalities in the brain has, however, resulted in the mitigation of criminal offenses, such as reducing charges of murder to manslaughter.

Studies of brain development have shown that early and chronic exposure to stress (e.g., abuse, neglect, violence) may cause physiological changes in the brain that impact the way a person responds to stress. Human brains under stress produce the hormone *cortisol*, which helps to return body functions to normal after a stressful event. However, repeated exposure to cortisol may result in decreased sensitivity to its effects and either contribute to criminality or contribute to a person's acceptance of being victimized. In addition, this research is supported by studies on the brain development of children raised in high-stress environments (inner city, urban, high-crime areas) that found enhanced fight-or-flight impulses among these children.

A recent study by Diana Fishbein in 2003 concluded that behavioral problems may originate in the *hypothalamic–pituitary–adrenal axis* (HPA) that connects the brain to the adrenal glands, which regulate the production of important hormones. Fishbein claimed that increased levels of cortisol, produced in response to stressors, cause the HPA to shrink and become ineffective. An ineffective HPA depletes cortisol and results in the inability to regulate emotions and behavior. A dysfunctional HPA may be caused by stress in childhood that impedes its development, or it may be caused by damage later in life.

Biosocial Perspectives

Some scholars who study criminal behavior began to synthesize sociological perspectives with biological perspectives. One of the most influential publications in this area was *Sociobiology: The New Synthesis*, written by E. O. Wilson in 1975. Wilson was among the first criminologists to express disillusion with current sociological and behavioral theories

by emphasizing that an individual was a biological organism operating within social environments. Publications by Dawkins in 1976 (*The Selfish Gene*) and by Ellis in 1977 (“The Decline and Fall of Sociology, 1975–2000”) illustrated criminological disillusion with purely sociological explanations and renewed hope for improved biological perspectives that would not operate under the faulty assumptions of earlier biological research. Major scientific developments from the 1950s to the mid-1970s (e.g., in the study of genetics) also contributed to the resurgence of interest in explanations of behavior with biological bases. Other advances in the mid-1980s led scholars to examine the brain more closely as a potential factor in criminal behavior.

Modern biosocial theories attempt to integrate beliefs about the sociological development of behavior (i.e., social learning, conditioning) with the biological development of the individual who engages in behavior. In contrast to earlier biological theories that imply the heritability of behaviors, biosocial theories suggest there may be a genetic predisposition for certain behaviors.

These predispositions are expressed in terms of biological risk factors associated with increased probabilities of delinquency and crime when paired with certain environmental (social) conditions. Various risk factors that have been evaluated include IQ levels and performance, attention deficit hyperactivity disorder, and conduct disorder. Although low IQ is not directly associated with crime or delinquency, individuals with lower IQs may experience frustration and stress in traditional learning environments, resulting in antisocial, delinquent, or criminal behaviors. A diagnosis of attention deficit hyperactivity disorder also has been associated with increased levels of delinquent and criminal behavior. However, some scholars point out that this is true only for individuals who also are diagnosed with conduct disorder. Both disorders can be traced to abnormalities in the frontal lobe, so it is difficult to disentangle the relationship of each to undesirable behaviors.

In contrast to risk factors that may enhance the probabilities of an individual engaging in delinquency and crime, biological protective factors, such as empathy, may inhibit this development. *Empathy* is the ability of one person to identify with another person and to appreciate another person's feelings and perspectives. Research has indicated that empathy is largely (68%) inherited. This biological tendency may counter the impact of biological risk factors. Research on these inhibiting protective factors is still quite sparse but may help explain why some people who have genetic predispositions toward delinquency and crime refrain from those behaviors.

Conclusion

Biological theories have evolved significantly with advances in our theoretical understanding of human behavior and in

our technological capabilities of measuring human biological characteristics and processes. Whereas earliest attempts to understand the relationships between biology and behavior focused on the outwardly observable, modern efforts are looking inward, to the chemical and structural foundations of our bodies. Contemporary biological theories also recognize the interactive relationship between internal biological events and external sociological events. Moreover, increasing awareness of the complex interrelationships among our environment, our biology, and our behavior is contributing to the development of a rich and promising epistemology of criminal behavior.

Our scientific advancements, however, still have not reached the level where we can definitively determine that antisocial, deviant, or criminal acts have biological roots or correlations. Increasing awareness of how our genes pass along (or do not pass along) our behavioral characteristics, of how our brain structures and functions are interrelated, of how our body chemistry affects and is affected by our behavior and reacts to environmental stimuli, and of how our development in a social environment impacts all of these biological processes will bring us closer to being able to predict behavior and therefore being able to better control it.

Care must be taken to separate the act from the actor and to avoid the atrocities of the past. As our ability to determine biological correlates of behavior expands, so too does the danger of using such information in unethical and inhumane ways that would stigmatize or punish people on the basis of what prohibited behaviors their biological profiles suggest they might do. It is hoped that progress in these areas of inquiry will parallel corresponding advances in our capabilities to prevent initial undesirable behaviors and to treat individuals who do behave undesirably because of biological or biosocial influences.

CLASSICAL PERSPECTIVES

ANDY HOCHSTETLER

Iowa State University

Classical criminology usually refers to the work of 18th-century philosophers of legal reform, such as Beccaria and Bentham, but its influence extends into contemporary works on crime and economics and on deterrence, as well as into the rational choice perspective. The entire range of social phenomena can be understood more or less accurately using models of economic transactions and the assumption that people make rational choices between opportunities to maximize their own utility. This was a foundational assumption of classical criminology. Sociological theory viewed crime through economic models, and this assumption is called *rational choice theory*. For criminologists, rational choice theory has origins in sociological theoretical thought and in various perspectives on economics and markets, but, more prominently, its influences are found in the classical school of criminology.

Rational Choice Theory and Get-Tough Policies

Drawing on the classical contention that man is a calculating creature, rational choice criminology begins with the assumption that behaviors of groups and individuals will reflect attempts to maximize pleasure and minimize pain. Theorists in this tradition hypothesize how varying conditions shaping the payoff of an endeavor in combination with varying utilities and desires will contribute to aggregate and

individual levels of crime. Most adherents agree that the utilities, or desirability, of activities are varying and subjective, so that crime may have attraction for some people that is not seen by others. There also is widespread agreement that the strength and quality of individual or group preferences can be taken into account in studying the occurrence of criminal behavior. Therefore, in criminology rational choice theory usually is a variant of expected utility theories and portrays the process of considering (or ignoring) criminal opportunities as part of a rational calculation based in part on subjective assessments wherein the expected costs and benefits of actions are considered.

The fundamental assumptions and methods associated with rational choice theory and its classical predecessor undergird a great deal of modern criminology, but its theoretical proponents and defenders have been in and out of fashion throughout criminology's history. The perspective fell from favor in the eyes of many criminologists in the last several decades in part because of its resonance with audiences prepared to "get tough" on crime through mass imprisonment and in part because it was seen as an attack on sociological, psychological, cultural, and structural explanations. It was often portrayed as a reductionist and simplistic theory due to the fact that proponents often emphasized the most obvious costs and benefits of crime commission, such as monetary payoff versus terms of imprisonment. Moreover, its foundational assumptions sometimes are critiqued for being so broad as to be meaningless. In very

recent years, however, the theory has attracted investigators drawn by its potential for making clear sense of why people commit crime and its ability to communicate the theoretical reasons behind research results to any audience. In contemporary forms, it also can conveniently integrate structural and perceptual models of offending, and the perspective easily makes sense of the use of a wide array of variables from multiple levels of analysis. The rational choice framework has great capacity for incorporating knowledge and techniques garnered from across the social sciences, because its central premises are extremely broad and conflict directly with few extant statements from other perspectives. In broad form, the rational choice perspective has as much potential for integrating knowledge from various spheres of criminology as does any other grand theory. For all its shortcomings, which derive mainly from economic assumptions about human and aggregate decision making and the tendency to focus on the most tangible variables, it makes efficient sense of complex questions.

Accompanying a more even-keeled political approach and more rigorous empiricism in criminology than was prevalent in more ideologically combative times has been a realization that there is nothing necessarily punitive in classical or rational choice theory and that therefore the perspectives should not be faulted when it is misapplied or misunderstood. Articles framed by the perspectives usually examine the possibility that punishment reduces crime, and often that is found to be the case in at least some examined conditions. However, for people who would use the perspectives as ideology to support getting tough on crime, the approach has as many inherent inconsistencies as convergences. Contemporary versions of rational choice specify countless complications of simple postulated relationships between increased punishment and decreased crime, for example. There clearly the rational choice tradition acknowledges that there are limited conditions under which one should expect punishment increases to lead to reductions in rates of crime or to impede individual decisions to commit crime.

Indeed, people who would turn to rational choice and classical theory for endorsement of punitive perspectives should know that they have opened themselves to attack from their desired theoretical bedfellows. This is because rational choice theorists and their classical forebears generally demand consistent and logical economic arguments and real evidence for the practicality and efficacy of state practices. Those who follow the tradition would evaluate the net payoff of punitive programs skeptically before determining them legitimate. Moreover, the tradition is closely coupled historically with utilitarian views of law wherein good laws are only those that can be enforced (which usually requires considerable popular legitimacy) and that lead to the general betterment. The latter, of course, is a difficult philosophical and empirical obstacle to surmount for people who argue that more punishment is needed.

The earliest classical theorists postulated that many punishments were necessarily irrational and excessive simply

because they would inevitably be ineffective in deterring crime. This fact still exerts significant influence in both rational choice and classical theorizing. Laws that are groundless, inefficacious, unprofitable, or needless are not good laws. If any convenient liaison between the classical, rational choice perspective and get-tough policies existed, it seems to have been temporary and probably not all that important for, properly modified, almost any broad ideology can inspire or be used to defend vengeful approaches to criminal justice.

Classical and Rational Choice Theorists and Their Heirs

Because the intellectual seeds for classical and rational choice criminology were sown in the 18th-century Enlightenment Age, many of the central questions and biases in the approaches were formed then. When the theories are recapped in textbooks, one is as likely to see reference to Beccaria and Bentham as to lesser sociological thinkers on choice and economics of crime of the last half century. Although the mathematics in contemporary applications sometimes are overwhelming to people who are unaccustomed to reading formulas, the thinking in older and newer versions of classical criminology at least is familiar. Much in the U.S. system of justice rests on the same foundations, and we live with the cultural and intellectual legacy spawned by the scholars who inspired classical criminology. The most important historical fact to keep in mind is that classical theorists were concerned primarily with reforming a primitive, irrational justice system that often was based on privilege and vengeful ritualistic traditions with a justice system that drew legitimacy from reason.

Early classical theorists knew that crime required rational management; they intended to calibrate the law and justice system for the task and generally agreed that the state should do no more than required to protect citizens and their property. The law should be pragmatic and effective. Precise visions of the philosophical underpinnings of rights, the law, and justice varied widely, but there was near-universal agreement among classical and enlightened thinkers of the 18th century that the deterrent value of the law should expend the least possible harm to society and to the individual; that is, the law should operate without undue or unneeded cruelty to offenders. According to this perspective, the costs of committing a given crime usually would slightly outweigh potential benefits, in order to tip the decisional scales toward compliance with the law; however, any punishment beyond that needed to accomplish this task is likely cruel and unnecessary. Classical visions eventually came to reflect the utilitarian ideas that balancing private and individual interests against public interest required optimizing liberty; minimizing harm; and, wherever possible, close correspondence between the two objectives. From inception, theorists contended that implementing rational law and legal measures required dispassionate judgment of what would be most effective and scientific

evaluation of attempted improvements. Crime control should be measured and its effectiveness evaluated objectively to ensure the proper balance of controllable costs and benefits of crime. Therefore, most evaluation research of legal changes and large-scale policy changes in the criminal justice system can be comfortably placed under the classical/rational choice tent.

The battles between those who rigidly adhered to purist sociological theories of crime (which generally focused on what is wrong with societies or other external social forces producing aberrant-thinking criminals) and those who took the side of a purist economics and rigid classical criminology are fading to intellectual history. As the latest generation of seasoned combatant in the fight leaves the field, one finds that their legacy is empirical support for multiple approaches to the problem of crime. It educates about the pitfalls of stringent and egotistical adherence to a single perspective and rigid defense of boundaries as much as it provides support for competing visions. With resulting invigorated faith in integration and cross-disciplinary approaches in criminology, rational choice and classical perspectives are on the cusp of revitalization and the perspective that may lead the way in sophisticated and integrated crime theorizing that is to come. The form of rational choice perspectives of the future will starkly contrast with the depictions of the school of thought that were presented in academic critiques and textbook accounts over the last several decades; these often pointed out that the theory was elementary and that it offered an unrealistic or artificial depiction of criminal choice as a rational/economic outcome.

Recent Studies

This possibility of reinvigoration of classically inspired thinking via rational choice in the form of a sophisticated, integrated, and formal theory of criminal behavior is signified by a study of high-risk youth in Denver (Matsueda, Kreager, & Huizinga, 2006). Matsueda et al. (2006) drew on longitudinal data to assess how perceived certainty of arrest is affected by individual characteristics (control variables, including age, race, residential stability, poverty) as well as theoretically inspired rational choice variables of experienced certainty (the ratio of experienced arrest or police questioning to crimes committed), unsanctioned offenses (the number of crimes committed by persons not questioned or arrested), and delinquent peers. Lagged perceived risk of arrest and self-reported risk preference (enjoyment of daring things) also were included. Perceived risk of arrest for theft and violence was regressed onto these variables.

Matsueda et al.'s (2006) results revealed that individuals who have not offended or been arrested overestimate the certainty of arrest. Experience of arrest certainty also leads to increased certainty estimates, revealing that offenders learn a desired lesson from being arrested for the crimes

they commit; those who are arrested most regularly resemble the naive in their high assessments of risk. Those who offend but go unsanctioned perceive that the certainty of arrest is low and tend to move farther and farther away from naïve offenders with more criminal successes. Delinquent peers lead to decreased estimates of the certainty of arrest. On the whole, these findings show that assessments of the rewards of crime are acquired by Bayesian learning; individuals begin with a prior subjective probability estimate of an event based on accumulated information and update probability estimates as new information is gained directly or vicariously. Perceptions are formed by experiences and approximate rational outcomes.

In the next part of their article, Matsueda et al. (2006) showed the effects of certainty estimates on offending. They predicted violence and theft commission in one wave of data with previous wave reporting of rational choice/perceptual variables including the positive experiences found in excitement from crime, seeing crime as cool, and committing crime and getting away with it. The downside of the criminal calculation is conceptualized as perceived risk of arrest (measured as perceived certainty by perceived utility) and lost investment in employment and grades. The authors assessed these effects, controlling for the effects of five measures of (1) neighborhood disadvantage, (2) basic individual control variables, (3) police contact, (4) risk preference, and (5) impulsivity. They also controlled prior delinquency to ensure that the temporal specification is clear and that current crime is a function of theoretically important variables instead of stable criminal behavior across waves.

Considerable support was found for a rational choice perspective on offending. This support is seen in significant effects for perceived risk of arrest as a cost and being seen as cool as significant benefits for both theft and violence; excitement from crime predicted theft but not violence. Perceived opportunities to commit theft and violence and get away with it also were significant predictors of both theft and violence in the expected direction.

This litany of findings is presented here only because it instructs on contemporary rational choice criminology and the attractions of the perspective today. The abstract lessons are that rational choice theory can guide the formation of intuitively valid, creative, and testable hypotheses that add to understanding of crime. The prospects for the perspective include understanding how experience and conditions shape thinking that makes some people more likely to offend than others, and this is the most promising line of inquiry for understanding why people commit, persist, or desist from committing crimes. More important for its future is that rational choice theory is completely compatible with dynamic and developmental perspectives that measure movement into, out of, and within criminal careers. Therefore, rational choice theory is commensurate with the core of contemporary criminological research: life course and developmental research. Any reader intrigued by studying crime over the life course or the prospects for

interfering in the sequences of thinking that contribute to higher chances of crime commission can find guidance in rational choice theory as well as in the more commonly used control theories.

As with many theories, however, the features that distinguish rational choice and classical perspectives from other camps can be difficult to see when they are used in integrated pictures of crime. It is safe to say that the degree to which adherents view crime as an outcome of a choice that is subject to general economic principles and that results from maximizing behavior on the part of decision makers distinguishes the camps from other areas of criminology. From this perspective, offending rates result from optimizing individuals' reactions to their estimates of incentives (referred to as *perceptual deterrence*, i.e., the role of an individual's perceptions of costs because these deter crime) and are aggregate results of individuals' assessments of costs and benefits. The offender traditionally is portrayed as a normal person (with no peculiar motives or individual defects that are thought to predispose crime) who responds predictably such that if probable costs exceed the probable benefits, he or she will not commit crime. Reflecting a tradition of methodological individualism, individuals' combined decisions to commit or abstain from crime on the basis of judgments of its net payoff are thought to explain variation in crime rates across space and time.

Gary Becker's work best represents the purist economic camp and thus may best represent a contemporary application of traditional classical thinking; it is grounded on the assumption that offenders are by and large normal and for the most part are responding to measurable incentive structures. Becker has been awarded a Nobel Prize and a Medal of Science, as well as a Presidential Medal of Freedom, and he is Distinguished Professor of Economics, Business and Sociology at the University of Chicago. Becker proposed what is now known as the *subjective expected utility model* of crime, which has proven to be surprisingly controversial. According to this theory, crime will be more likely if the individual's perceived expected utility (expressed in monetary terms) for criminal behavior is greater than the expected utility of some legal alternative. This model is often represented mathematically with the following formula: $EU = pU(Y - f) + [1 - P]U(Y)$, where EU represents the expected utility from the behavior, p is the probability of punishment, and U represents the utility (the severity) of costs or benefits. Becker contends also that people who might consider crime calculate the following: (a) practical opportunities of earning legitimate income, (b) amounts of income offered by these opportunities, (c) amounts of income offered by various illegal methods, (d) probabilities of being arrested for illegal acts, and (e) probabilities of punishment if caught. The act or occupation with the highest discounted return is likely to be chosen (Sullivan, 1973). As an economic purist, Becker asserts provocatively that there is little reason for theorizing that treats offenders as if they have a special character that leads them to crime. Becker extends his logic to

conclude that the most prominent theories of motivation in criminology are not needed; basic economics addresses their problem sufficiently. Criminal offenders are normal, reasoning economic actors responding to market forces. This dogma understandably leaves him out of favor with many sociologists of crime who specialize in other criminological theories and, as one might imagine, he is not a favorite of criminal psychologists either. If classical criminology theory as used by Becker is accurate, then one should expect that rates of crime will be stable if the costs and benefits of it remain so; however, in modified versions that are endorsed most often among scholars who claim rational choice as their perspective, allowance is made for the fact that the population of likely criminals and prevalence of criminal thinking might also vary.

Further Perspectives on Deterrence

Underlying much writing in the classical tradition is the objective of determining what a reasonable system of justice would look like, and this leads to the assessment of the effects of varying policy on criminal behavior. This includes evaluation of what the optimum level of enforcement and sanctions should be and whether deterrent measures have worthwhile prospects. Following the belief that criminal law must minimize the social cost of crime, and that social costs are calculated by adding the harm crime causes and the cost of punishment, researchers who focus on deterrence, which is an offshoot of classical criminology, analyze penalties and their effects.

Research that does not allow for varying perceptions of costs and benefits across types of would-be offenders, places, or time periods are referred to as *objective deterrence* studies. The study of the relationship between imprisonment rates and crime rates, for instance, usually falls within this category. In contrast, *perceptual deterrence* theorists focus on varied perceptions of costs and benefits across types of would-be offenders, places, or time periods. In practice, the distinction between the objective deterrence and perceptual deterrence/rational choice perspectives also rests on the former's focus on aggregate variation and tendency to use macrolevel variables that reflect variation in opportunity for crime and spatial and temporal differences in payoff and punishment. Objective deterrence theorists are likely to use the most general economic variables and predictions that emphasize variation in state policies and economic conditions, whereas perceptual deterrence/rational choice theorists are more likely to focus on individual variation in crime and varying individual criminal propensity. They also are more likely to incorporate a wider array of variables into explanations, often drawing insight from traditional domains of psychology and sociology.

A small but increasing share of the voluminous literature on deterrence reflects emerging interest in modeling formally and testing game theoretic and other exchanges occurring between individuals who would deter crime and

those who would commit it (Fender, 1999). One notion is that aggregate offender (and state) choices reflect the ongoing mouse-and-mousetrap relationship as crime fighters and the people who might consider illegal acts learn and react to changing environments of exchange. There also is increasing theoretical attention to the possibility that lawmakers can use deterrent penalties to shift moral and cultural qualms about crime and change the public's cost-benefit analyses as a result (Dau-Schmidt, 1990). The integration of game theory and other dynamic views on feedback between penalties and assessments of crime into classical criminology is in its infancy, however. Investigating how changes in policies affect the subsequent behavior of population aggregates, such as by examining the effect on drunk driving of stringent enforcement of laws prohibiting drunk driving and accompanying public information campaigns (they worked), or the number of crimes prevented by executions (a highly contested series of findings), remains the thrust of deterrence research.

If there are contingencies in efforts to deter crime by raising its costs, the most apparent is that the point of diminishing return for investing in deterrent efforts varies by crime, probably according to the size and characteristics of the population that remains undeterred when a new policy is imposed. Crimes committed by many people, by non-desperate or lightly motivated people, or by legally informed people and crimes with currently lenient penalties must be easier to reduce with new measures than are crimes committed by a few desperate persons who are capable of ignoring penalties that already are stiff. In the former case, the easy work is yet to be done. Partially because natural consequences and shame are powerful deterrents (Pratt, Cullen, Blevins, Daigle, & Madensen, 2006), relatively rare crimes that have tremendously devastating natural or informal consequences are difficult to deter further by formal means. For some of these reasons, the great classical criminologist Beccaria famously observed that 18th-century laws forbidding suicide necessarily are ineffective. Crimes with already stiff penalties also are unlikely to effect significant additional deterrence by adjusting formal penalties upward; some people do not scare easily. Even those who might be scared should they consider a consequence may not be deterred if, at the moment of decision, that consequence is not recalled, or if they are so intent on committing an act that little else matters.

Only a few criminology scholars use experimental methods to assess whether rewards and punishment affect cheating or risk-taking on assigned tasks (Ward, Stafford, & Gray 2006). There are numerous studies in which participants of varying background have put pen to paper to explain how they would evaluate costs and benefits presented in vignettes and have answered background questions about their own decisions and experiences to see whether they are able to predict costs and benefits. When presented vignettes that contain calculable and finite costs and benefits, respondents usually answer accordingly, leading to the conclusion that the decision to commit crime generally is predicted by

cost-benefit assessments. On the whole, and with many caveats, there can be no doubt, on the basis of the results of this research, that deterrence works when other relevant factors can be controlled and that there is considerable rationality undergirding criminal choice.

Similar survey techniques for examining criminal decisions include exercises in which known offenders, responding to vignettes, describe in detail what they consider when deciding to commit or selecting real crimes. There also have been interviews about rationality in the target selection process and on how offenders sequentially proceed through decisions leading to crime. Here, it has been confirmed what researchers who study target selection and routine activities approaches have already shown by survey and geographic methods: Where crime is easy to commit and the odds of getting away with something are made high by environmental arrangements and circumstance, offending is likely.

Costs and Benefits: The Economic Model

A case can be made that a general and accurate picture of crime can be presented with grand economic theories containing only the most apparent variables representing the market for crime. This form of theorizing holds most true to the classical tradition. Analyses of aggregate variation tend to smooth out some of the complexities and detail found in decisions; however, such analyses generally attempt to model the effects of only a few variables that might influence the rate of occurrence of crime generally. The trade-off of such a general approach is that it necessarily obscures important details and peculiar thinking that affect decisions in many offenses. This empirical-theoretical divide in rational choice/classical literature is not unique to criminology. Economists might examine how purchasers respond to price changes by graphing the number of purchases by increasing prices, and that approach obviously can provide general knowledge on the subject. However, the microconsiderations of real buyers and their idiosyncrasies are more likely to be found in interviews, captured in surveys, or seen in laboratories by observing would-be consumers. Marketers might be more intrigued by the information gained in the last approach. The analogy reveals that aggregate and bottom-up studies of decision making approach the same phenomena from different angles and levels of analysis.

These divides are revealed in debates among researchers who study crimes as economic decisions. Despite debates, diverse approaches are commensurable, and in some cases each type of analysis might incorporate variables discovered in models done in the other. As is often the case with large numbers, many idiosyncratic influences on decisions cease to exist, but both normal and exceptional psychological patterns can be discovered and modeled in aggregate data. In fact, almost all contemporary economists recognize that there is a complex psychology of markets that incorporates

external variables and logics but that affects the aggregate outcome significantly. It is widely accepted that learning, ignorance, convenience, and the tendency to satisfy (as opposed to maximize) all affect choice.

Some scholars who attempt to model relevant and recurring behavioral components into macrolevel models are at the forefront of the discipline of economics. There are subfields devoted to decision making under uncertainty and prospect theory, which models heuristic shortcuts that depart systematically from principles of probability shaping choice. There have also been advances in theorizing behavioral/economic approaches to law, which attempt to improve models of rational choice by relaxing assumptions that people are only rational optimizers of self-interest and by incorporating complexities of learned strategies for decision making under uncertainty. Criminology has far to go in understanding how even the simplest intersections of psychology, decision-making considerations, and changing markets influence crime and further still before it can incorporate cultural shifts and changing preferences into traditional aggregate economic or classically inspired models.

There is an emerging consensus within the classical camp, especially among legal scholars with an interest in moral shifts, that crime rates probably reflect fluctuation in the size and tastes of a likely customer base as well as in changing estimates of incentives and sanctions by the general population (Cooter, 2000a, 2000b). Crimes with payoff that objectively is stable over time, for example, might ebb and flow in their perceptual attractiveness in part because of the public's multifaceted response to law. This view acknowledges that, if there is a market for crime, there may be limited numbers of participants under normal historical conditions. However, many citizens will ignore completely variation in the factors intended to raise or lower net criminal benefits, for one reason or another. There is almost no reason to think that the size of the likely offender population is stable or contingent only on economic variables, and models of crime that want to increase explained variation probably should take that into account. There is less reason for assuming that individual offenders' thinking is intractable rather than developed over time and contingent on varying ways of thinking, events, and previous outcomes.

Many of the complications of applying the rational choice perspective are due to preferences, commitments, and mental impediments that can influence choice and make crime more or less likely. Preferences, commitments, and mental impediments may be disproportionately characteristic of identifiable groups of persons that are prone to offending. Individuals or categories of people may desire things that are not apparently objective costs or rewards of a given decision for all observers. Advertisers, for example, know that they can play on consumers' irrational preferences by cleverly and expensively packaging goods even when that packaging is thrown away immediately

on purchase; marketers know that some consumers are more enticed than others and how to play to the tastes of particular groups. Preferences affect what is chosen when one is confronting criminal opportunity as much as they determine what persons choose when deciding whether to purchase or walk away from a product in a store. For example, problem gamblers have not only an increased desire for arousal that comes from the activity but also increased expectations that gambling will result in positive and arousing experiences, as has been shown in a sample of criminal offenders (Walters & Contri, 1998). Therefore, rational choice applications that fail to account for varying tastes and sensations related to crime may be neglecting important variables and limiting explanatory power. Despite the admonition that explanations of crime that focus on abnormality are superfluous by advocates of pure economics, it is likely that offenders are drawn to elements of criminal activity in a way that others are not.

Individuals or groups also may have ways of thinking that skew their analysis of costs and benefits, apart from utilities. It is now widely accepted that there are thinking mistakes associated with addiction, for example. These mistakes include a willingness to act without full information, mistaken retention of practiced behaviors in simple tasks, and the discounting of future consequences. If one looks to gamblers, and experiments that emulate gambling, one can see that a great many people are overoptimistic about their ability to calculate outcomes, consider sunk costs errantly, are too loss averse to play rationally, see only the most available options, and misinterpret near-misses as near-wins instead of as losses. Indeed, the earliest statements of classical criminology recognized that the severity of punishment generally is discounted according to the amount of time (celerity) until it will be imposed, implying that the discount might be greater for some than others. There is a long and continuing history of examining whether offenders discount future costs more than nonoffenders and of extrapolating the implications for law (Listokin, 2002, 2007). Discounting potential negative consequences at greater rates than others may be one manifestation of impulsivity, a construct increasingly integrated into individual-level analyses of crime. Many of these analyses are inspired by and designed to improve on earlier versions of rational choice and classical criminology.

Crime, Self-Control, and Patterns of Influence

A currently prominent general theory of crime that claims descent from classical criminology and takes significant inspiration from rational choice perspectives asserts that offenders are likely to have low levels of self-control. They are hyperphysical, self-centered, impulsive, hot-tempered risk-takers who enjoy simple, unchallenging tasks (Gottfredson & Hirschi, 1990). The opposite of these characteristics is termed

self-control. For persons with low self-control, crime is a particularly attractive prospect. There is considerable evidence in psychology and criminology that some persons are predisposed by such tastes for offending. The source of the thinking problems may lie in inattentive parenting. In the language of rational choice perspectives, individuals without self-control, which is conceptualized as a stable characteristic, prefer crime and similarly present-oriented activities more so than other individuals. Given equivalent costs and benefits, we should expect people who have exhibited limited self-control to be more likely to choose crime than those who have not. Such impediments, in combination with the fact that many active criminals are intoxicated much of the time and the significant percentage of criminals who are on the lower end of intellectual abilities, might indicate that offenders occupy the high tail of the curve for impediments to reason. In fact, in a recent restatement on the measurement of self-control, Hirschi (2004) suggested that self-control is best measured as the number of costs considered during an offending decision, coupled with the perceived importance of these costs. Clearly, Hirschi is suggesting a correspondence between self-control and rational choice as explanation of crime.

Preferences that lead to crime need not be the ones that lead to stupid decisions, and they need not be especially peculiar. Some are widely shared and can lead to other healthy outcomes. For example, base desires for money and material trappings underlie a great deal of offending but also can lead to hard work. McCarthy and Hagan (2001) showed that a disposition for risk taking and competence interact to raise the rewards of crime, much as the characteristics lead to successful entrepreneurship. This suggests that some people are suited to crime and gaining its returns, just as some are suited to becoming entrepreneurs. It is a small inference to assume that the latter might find crime more attractive than criminals who are destined to achieve low returns. In a study of predictors of white-collar crime, N. L. Piquero, Exum, and Simpson (2005) showed that a desire for control is correlated with such crimes. It is also known that some rewards of crime are interpreted differently by known offenders and others; for example, subculture dictates lead some offenders to interpret interpersonal confrontations using a particular set of costs and benefits that likely will elude people outside their cultures. People who stand up for themselves might also be rewarded by deference from those who would harass them otherwise.

It might be said that some people have a strong preference for law abidance and some do not. Where one falls on the spectrum of preference for and against illegality can determine attentiveness to rational choice considerations. Likewise, there is considerable reason to think that criminally prone individuals are influenced differently by sanctions (Wright, Caspi, Moffitt, & Paternoster, 2004). Greg Pogarsky's (2002) survey of 412 university students about drinking and driving is illustrative of this point. After reading a vignette about deciding to drive from a bar or

find another means home after drinking too much, students estimated the chances of being caught and the severity of the punishment if they were. They were then provided with the same vignette and asked whether they would drive if they knew there were no chance of being caught. Students were classified into those who would not consider drinking and driving at all (acute conformists), those whose chances of drinking and driving increased when they had knowledge that they would get away with it (deterables), and those who reported that they were more than likely to offend in both the first instance and with no risk of being caught (incorrigibles). Acute conformists were influenced heavily by self- and social disapproval. Predictors were analyzed further by comparing incorrigible and deterable offender categories. It is important to note that incorrigibles' offending likelihood was not subject to certainty or severity estimates of the varied consequences. The effects of severity operated strongly on deterable students. Certainty of being caught and self-disapproval had significant effects in the expected directions. This serves as one of the many sources of evidence for the interaction of rational choice variables with other variables and what should by now be an obvious point: There are patterns of influence for rational choice variables in subcomponents of the population that affect the general population differently.

Commitments are externally created considerations that are imported into a discrete decision; they would have little bearing on its outcome and would not shape immediate costs and benefits except for the fact that the people who harbor them assign them importance. These people's behavior often seems irrational to people who are not aware of the outside obligations affecting their decisions. Imagine a rational choice theorist attempting to understand when a loan shark shoots the indebted by looking only at a particular transaction with a deadbeat. An investigator might assume that the loan shark will do what maximizes the chances of financial return. However, it is necessary to understand that the usurer has an image to uphold that allows the work to be done. Apart from the job and best strategy for sustaining a career, if the loan shark has promised that delinquent borrowers will be hurt, the general value of credibility for interpersonal exchange might lead to an unfortunate result. A promise is a promise.

Of course, commitments also can work to impede crime. Travis Hirschi asserts that his control theories of crime are extensions of classical theory and highly compatible with rational choice theories. In calculating the costs of crime, individuals consider their investments in conformity and institutions. Sally Simpson has conducted multiple studies that bear on rational choice and prospects for deterrence among people with differing opinions. In one such study (2002), she administered surveys to business students and corporate executives containing vignettes of white-collar decision-making contexts and possible criminal responses. Estimates of personal benefit predicted intentions to offend, as did risk perceptions.

Respondents who saw opportunity for career advancement and thrills also were more likely to choose crime than others. Scores on an ethical reasoning scale; shame; and the possibility of informal sanctions from family, friends, and business associates affected criminal intention. The threat of being fired or corrected by superiors decreased intent, and being ordered to commit crime increased intent. Most relevant for understanding the place of commitment is that for highly moral “good citizens,” neither threat of sanctions nor other variables made much difference. Respondents who scored low on personal morality (low commitment to a moral code) were another matter; they were deterred by threat. Evidence for similar interaction between morality (self-disapproval, capacity for shame) and perceived opportunity has been reported by many other researchers.

Conclusion

Perspectives that imagine crime to be the outcome of a deliberative calculation have limitations. They sometimes contain an uncomplicated view of the rational man as *homo economicus*. It is clear that the strengths of classical criminology and rational choice are not found in their sophisticated depiction of the intricacies and diverse workings of human cognition and psychology. The mind and meaning are not where the core of tradition suggests that investigators look for answers about the occurrence and distribution of crime. Moreover, the fact that crime is often a stupid mistake leads many scholars to incorrectly and intuitively believe that rational choice perspectives miss the mark on the basis of the colloquial use of the word *rational* as a synonym for prudent, careful, or cautious. No reasonable rational choice or classical camp scholar has ever contended, however, that deliberating criminals choose their courses of action carefully. All scholars recognize that decisions and options can be constrained and that most daily and significant decisions are not made with ledgers in hand. In fact, recent research in neuropsychology and the decision-making sciences suggests that human decision making is aided, for instance, by the individual being in an optimal state of emotional arousal—that the arousal state is not too “hot” so as to make rash decisions but not so “cold” as to be unmoved by potential consequences (see Damasio, 1994). Similarly, emotional processing of information has been demonstrated to aid decision making by allowing heuristic “shortcuts” in the decision process. However, no perfect knowledge, lightning-fast calculation, or any of the other caricatures of economic theory are required to make efficient sense of crime with economic logic and methods (Becker, 1968).

Even rational choice theories, which typically add complexity not found in traditional classical models, sometimes are criticized for being too general. However, rational choice theory is best seen as a “framework, a rubric or a family of theories” that serves to “organize

findings, link theoretical statements and logically guide theory construction” (Hechter & Kanazawa, 1997, p. 194). In criminology, attempts to dismantle or criticize the general perspective rather than specific hypotheses derived from it might be particularly futile, because rational-choice theorists acknowledge that they support the perspective for its sensitizing principles and because it suggests variables that one ought to examine. Scholars who adhere to even purist, or thin, versions of rational choice and classical depictions of crime are not blinded to the way things really are, or to the complexities of crime and cognition, inasmuch as they have clear notions about where to begin: with a focus on the content and process of individuals’ decisions to engage in criminal behavior as well as the belief that cost–benefit analyses occur on the part of the offender.

CRITICAL CRIMINOLOGY

DAVID O. FRIEDRICHS

University of Scranton

C*ritical criminology* is an umbrella term for a variety of criminological theories and perspectives that challenge core assumptions of mainstream (or conventional) criminology in some substantial way and provide alternative approaches to understanding crime and its control. Mainstream criminology is sometimes referred to by critical criminologists as *establishment, administrative, managerial, correctional, or positivistic* criminology. Its focus is regarded as excessively narrow and predominantly directed toward individual offenders, street crime, and social engineering on behalf of the state. The critical criminological perspectives reject the claims of scientific objectivity made on behalf of mainstream criminology as well as the privileged status of the scientific method. Although some critical criminologists apply an empirical approach with the use of quantitative analysis, much critical criminology adopts an interpretive and qualitative approach to the understanding of social reality in the realm of crime and its control. The unequal distribution of power or of material resources within contemporary societies provides a unifying point of departure for all strains of critical criminology.

Critical criminologists tend to advocate some level of direct engagement with the range of social injustices so vividly exposed by their analysis and the application of theory to action, or *praxis*. All the different strains of critical criminology hold forth the possibility of effecting fundamental reforms or transformations within society that promote greater equality and a higher quality of life for the disadvantaged and the disenfranchised, not just the

privileged members of society, and a more humane, authentic society for all. The dominant forms of social control—from policing practices to penal policies—are a common target of criticism as central to perpetuating injustices, as profoundly biased, and as counterproductive in terms of achieving positive changes in individuals as well as social conditions.

Crime and its control are major preoccupations of people everywhere. Public perceptions of crime and its control are in many respects distorted by media representations and the agendas of the governing elites. The immense significance of critical criminology, then, lies in its capacity to expose the conventional myths about crime and its control and to provide an alternative basis for understanding these tremendously consequential dimensions of our social existence.

The historical origins of critical criminology, its principal contemporary strains, and some of its major substantive concerns are identified in the paragraphs that follow. In addition, some speculation is offered regarding the future prospects of critical criminology.

Origins of Critical Criminology

Contemporary critical criminology has its roots in a range of theoretical perspectives that have advanced a critique of both the existing conditions in society and the conventional or established theories that claim to explain society, social phenomena, and social behavior. Marxist theory has

been one source of inspiration for some influential strains of critical criminology, although it has been a common error to characterize all critical criminologists as Marxists or neo-Marxists. Karl Marx and his close collaborator Friedrich Engels did not develop a systematic criminological theory, but it is possible to extrapolate a generalized Marxist perspective on crime and criminal law from their work. The ownership class is guilty of the worst crime: the brutal exploitation of the working class. Revolution is a form of counterviolence, then, and is both necessary and morally justified. The state and the law itself ultimately serve the interests of the ownership class. Human beings are not by nature egocentric, greedy, and predatory, but they can become so under certain social conditions. Conventional crime is, in essence, a product of extreme poverty and economic disenfranchisement and of “false needs” and the dehumanizing and demoralizing effects of the capitalist system. However, conventional crime is neither an admirable nor an effective means of revolutionary action, and all too often it pits the poor against the poor. Marx also regarded crime as “productive”—perhaps ironically—insofar as it provides employment and business opportunities for many. In an authentically communist society the state and the law will wither away, with the formal law being replaced by a form of communal justice. Human beings will live in a state of harmony and cooperation, without crime.

For most of the history of criminology, rather few criminologists specifically adopted a Marxist framework. The Dutch criminologist Willem Bongers was an exception to this proposition. Although he rejected dogmatic Marxism, Bongers—especially in *Criminality and Economic Conditions* (1916)—sought to show how a political economy organized around “private property” promoted crime. Some later neo-Marxist or radical criminologists were critical of Bongers for adopting a positivist and empiricist approach to the study of crime and for his attention to the “correction” of lawbreakers, but within the context of his time Bongers was certainly a pioneering figure in recognizing the value of a Marxist framework for the understanding of crime. Georg Rusche and Otto Kirchheimer, in *Punishment and Social Structure* (1939), also drew on a Marxist approach in advancing the thesis that punishment in contemporary society could be viewed as a form of control of the laboring class in a capitalist society. Although Rusche and Kirchheimer were not trained as criminologists, some radical criminologists in a later era drew inspiration from their work. Indeed, some other scholars over the years who were not criminologists have had a significant impact on radical and critical criminologists. For example, the French social historian Michel Foucault, in *Discipline and Punish* (1979), set forth an influential interpretation of the ideological purposes of penal practices that has been quite widely cited by critical criminologists.

Although many sociologists and criminologists continue to recognize the power of some basic dimensions of Marxist theoretical analysis to make sense of the world, it

is also indisputably true that any invocation of “Marxist” carries with it a lot of baggage in the form of association with the immense crimes committed—primarily during the 20th century—in the name of a claimed Marxist or communist society. Accordingly, it is difficult for some criminologists to be receptive to the potent explanatory dimensions of Marxist theory and concepts independent of the perverse applications of Marxist analysis in some historical circumstances.

In the American tradition, there have always been people who have recognized that the law and the criminal justice system it produces reflect disproportionately the interests of the privileged. American versions of critical criminology have drawn on a tradition of populism, anarchist thought, the civil rights movement, contemporary feminism, and other progressive endeavors that have challenged the dominance of white men of means, big business, and the status quo in general. At least some early American criminologists reflected such influences. Edwin H. Sutherland was arguably the single most important American criminologist of the 20th century. Although not a radical in a conventional sense, Sutherland was influenced by the American populism of his native Midwest and was outraged by stock market manipulators who helped bring about the famous 1929 stock market crash and the economic depression that followed. In 1939, Sutherland introduced the notion of white-collar crime into the field of criminology. Criminologists up to that time had focused on conventional crime and, disproportionately, the crimes of the poor. Sutherland recognized that the middle and upper classes of society are also significantly involved in criminal endeavors, and he especially examined crimes carried out on behalf of rich and powerful corporations.

Most of the criminology and criminological theory produced into the 1960s addressed the causes of crime and criminality within a framework that did not challenge the legitimacy of the law and the social order. This began to change in the 1960s. *Labeling theory*, which emerged out of symbolic interactionism, shifted attention away from criminal behavior to the processes whereby some members of society come to be labeled as deviants and criminals and to the consequences of being socially stigmatized. Many critical criminologists were influenced by this approach, although they ultimately criticized it for its focus upon the “microlevel” of social behavior and its relative neglect of the broader societal and political context within which the labeling process occurs.

The 1960s as an era is associated with the intensification of various forms of conflict within society, so it is not surprising that the core theme of conflict received more attention during this era. Thorsten Sellin, a socialist in his youth, produced one early version of a criminological approach that focused on the centrality of conflict in the 1930s, and George Vold subsequently produced a pioneering criminological theory textbook in the 1950s that highlighted the significance of group conflict for the understanding of crime and its control. In the 1960s, Austin Turk, Richard Quinney,

and William J. Chambliss (with Robert T. Seidman) introduced influential versions of conflict theories into the field of criminology. Conflict theory focuses on the unequal distribution of power within society as a fundamental starting point for the understanding of crime and its control, with some groups better positioned than others to advance their interests through law. Conflict criminology provided a basic point of departure for radical criminology and, subsequently, critical criminology. Turk has been a proponent of a “non-partisan” version of conflict theory, which takes the position that the central role of power and authority in defining crime and guiding criminal justice processes can be assessed empirically without identifying with a particular political agenda. Quinney, following the publication of his seminal conflict theory text, *The Social Reality of Crime* (1970), moved through a number of stages of theory development, from radical to critical to beyond. Chambliss also subsequently became more directly identified with radical and critical criminology.

The era of the 1960s (extending from the late 1960s to the early 1970s) was a period of much social turmoil, including, for example, the emergence of black power, feminist and gay rights movements, and consumer and environmentalist movements; the growing opposition to the Vietnam war; the surfacing of a highly visible counterculture and illicit drug use; and the embracing of radical ideology by a conspicuous segment of college and graduate students. By the late 1960s, a full-fledged radical sociology had emerged that challenged premises, methods, principal concerns, and corporate or governmental affiliations of mainstream sociology. C. Wright Mills (who died prematurely in 1964) was one seminal source of inspiration, and parallel radical approaches were developed in many other cognate disciplines, including history, economics, and political science. All these developments both influenced and were reflected within the field of criminology. Criminologists who became disenchanted with the limitations of a dominant liberal response to the problem of crime, with its emphasis on incremental social reforms and rehabilitation programs, were searching for an alternative approach to understanding crime and criminal justice. Some prominent faculty at the University of California (Berkeley) School of Criminology were key figures in the promotion of a radical criminology, which contributed to the school being shut down in 1974. Herman and Julia Schwendinger, affiliated with this school, published an influential article calling for an expansion of the scope of criminological concern beyond the parameters of state-defined crime and increased attention to other identifiable forms of social harm. However, self-identified radical criminologists continued to encounter many forms of resistance and some barriers to professional advancement. Research funding was less available to support the projects of radical criminologists than it was for mainstream criminological research that was perceived as useful in addressing conventional forms of crime.

A distinctive radical criminology—and a Union of Radical Criminologists—emerged in the early 1970s. Journals such as *Crime and Social Justice* and *Contemporary Crises* were important venues for radical criminology scholarship during this time. The Center for Research on Criminal Justice’s *The Iron Fist and the Velvet Glove* (1970) exemplified the radical criminological ideal, insofar as it was an essentially Marxist analysis of the police, collectively written, and oriented toward praxis, with a section on organizing for action. Quinney was surely the best known, most frequently cited, most prolific, and most controversial radical criminologist of this period. In several books published in the 1970s—*Critique of Legal Order* (1974), *Criminology* (1979), and *Class, State and Crime* (1980)—Quinney applied a neo-Marxist interpretation of capitalist society to an understanding of crime and criminal justice. In *Critique of Social Order*, for example, Quinney argued that law in a capitalist society functions to legitimate the system and to facilitate oppression and exploitation. He asked whether we really need law and whether we might be better off without it. In 1982, Quinney coedited (with Piers Beirne) a noteworthy anthology, *Marxism and Law*.

By the end of the 1970s, Quinney had become somewhat disenchanted with the conventional concerns of academic scholars and of criminologists specifically. In the years that followed, he pursued a range of projects, often wholly removed from criminological concerns, including explorations in phenomenology; existentialism; critical philosophy; liberation theology; Buddhism; and autobiographical, reflexive work. However, he also made seminal contributions to the establishment (with Harold Pepinsky) of a major strain of critical criminology called *peacemaking criminology*, and several generations of radical and critical criminologists have drawn inspiration from his work.

Other criminologists during this period also made influential contributions to the establishment of a radical criminology: In the United States they included William J. Chambliss, Tony Platt, Paul Takagi, Elliott Currie, and Raymond J. Michalowski, among others. In many other countries versions of radical criminology surfaced as well. Ian Taylor, Paul Walton, and Jock Young’s *The New Criminology: For a Social Theory of Deviance* (1973), which emerged out of meetings of the National Deviancy Conference in the United Kingdom, was a widely read attempt to expose the limitations of existing theories of crime and to construct a new framework based on a recognition of the capacity of the capitalist state to define criminality in ways compatible with the state’s own ends. The authors of this book called for a form of criminological theory and analysis that operated independently and not as a handmaiden to repressive state policies.

By the end of the 1970s, much of the initial radical political and cultural energy of the earlier part of that decade had disintegrated. A book entitled *Radical Criminology: The Coming Crises* (1980), edited by James Inciardi, was a

controversial collection of critical (and appreciative) interpretations of radical criminology. If the radical criminology that emerged during the 1970s was never a fully unified enterprise, it became even more fragmented during the course of the 1980s. Going forward from that period, the term *critical criminology* increasingly displaced radical criminology, and the emergence of distinctive strains of critical criminology became increasingly evident. Scholars who adhere to these various strains of critical criminology are united in that they draw some basic inspiration from the conflict and neo-Marxist perspectives developed in the 1970s, in their rejection of mainstream positivistic approaches as a means of revealing fundamental truths about crime and criminal justice, and in their commitment to seeking connections between theoretical and empirical work and progressive policy initiatives and action. Although some critical criminologists continue to work within one or the other of the earlier conflict and neo-Marxist perspectives, many others have become more closely identified with critical perspectives that have emerged (or been applied to criminological phenomena) more recently.

The recent era has been regarded as both politically and culturally more conservative than the era of the 1960s, but critical criminology has been a fairly vigorous presence within criminology, despite—or perhaps because of—this less receptive societal environment. The Division on Critical Criminology, which publishes the journal *Critical Criminology*, has been an especially large division within the American Society of Criminology since its establishment in 1988. Every year, the Division on Critical Criminology attracts recruits among new criminology graduate students who recognize that their ideological orientation and research interests are at odds with those of mainstream criminology.

In the sections that follow, the principal strains of critical criminology are identified and described, along with a number of more recent emerging strains.

Principal Strains of Critical Criminology

Peacemaking Criminology

The contemporary form of peacemaking criminology is principally the product of two well-known, prolific, and highly original critical criminologists: Richard Quinney and Harold Pepinsky. They have collaborated to put together the premier reader on the subject, *Criminology as Peacemaking* (1991). The basic themes of a peacemaking criminology have been concisely identified as follows: connectedness, caring, and mindfulness. Personal suffering and suffering in the world are taken to be inseparable. We should avoid personalizing evil and constructing false schemes that pigeonhole human beings as honorable citizens or reprehensible criminals. Instead, we should focus

on our common humanity and choose affirmative ways of reaching out to and interacting with others. Responses to the problem of crime must begin with attending to ourselves as human beings; we need to suffer with the criminal rather than making the criminal suffer for us. Altogether, peacemaking criminology calls for a fundamental transformation in our way of thinking about crime and criminal justice.

Peacemaking criminology is by any measure a heretical challenge to the dominant assumptions of mainstream criminological perspectives. It can be criticized as a form of utopianism, but at a minimum it serves as a provocative antidote to the explicit or implicit cynicism or pessimism of other criminological perspectives. Peacemaking criminology has some affinity with an *anarchic* or *abolitionist criminology*, but this latter perspective is more directly associated with the controversial proposition that we would be better off without a formal state (and its laws) and would be better off without prisons and a formal justice system. Peacemaking criminology can also be linked with the expanding *restorative justice movement*, which calls for a shift away from a retributive justice system that focuses on identifying and punishing perpetrators of crimes and toward a system that focuses on repairing harm through a cooperative endeavor involving the accused, the victim, and the community. The restorative justice approach has been embraced by some portion of the mainstream (and even conservative) community, and at least some critical criminologists believe it has been co-opted by the criminal justice system. Others, however, believe that it continues to have progressive potential. The work of peacemaking criminologists has been directed toward sensitizing people to counterproductive, inherently unjust responses to conventional forms of crime.

Postmodernist Criminology

Although a *postmodernist criminology* has been identified as one strain of critical criminology, postmodern thought itself is by no means necessarily linked with a progressive agenda; on the contrary, much postmodernist thought is viewed as either consciously apolitical or inherently conservative and reactionary.

Any attempt to characterize a postmodernist criminology—or postmodern thought itself—encounters difficulties. It can be best described as a loose collection of themes and tendencies. Postmodernists reject totalizing concepts (e.g., the state), they reject positivism, and they reject the potential of collective action to transform society. Postmodernism contends that modernity is no longer liberating but has become rather a force of subjugation, oppression, and repression. For postmodernism, language plays the central role in the human experience of reality. The postmodernist “deconstruction” of texts exposes the instability and relativity of meaning in the world. Within critical criminology specifically, Stuart Henry and Dragan

Milovanovic have produced a pioneering effort—which they call *constitutive criminology*—to integrate elements of postmodernist thought with the critical criminological project. They are especially concerned with highlighting the role of ideology, discursive practices, symbols, and sense data in the production of meaning in the realm of crime. We must, they contend, understand how those who engage in crime, who seek to control it, and who study it “co-produce” its meaning.

Feminist Criminology

This perspective has especially focused on exposing the overall patterns of patriarchy and male dominance in all realms pertaining to crime and the legal system. Whatever their differences, feminists such as Meda Chesney-Lind, Carol Smart, and Kathleen Daly have been quite united in identifying and opposing social arrangements that contribute to the oppression of women. Direct forms of male violence (e.g., rape and spouse abuse) targeting women inevitably have been a major preoccupation of feminist criminology. In addition to those forms of crime that specifically and directly target females, feminist criminologists have also sought to demonstrate the broader vulnerability of females to a range of crimes not in this category, such as the multinational corporate exploitation of labor in sweatshops in developing countries. At least some feminist criminologists have also focused on the nature of female involvement in criminal behavior and the social and cultural forces that have led to a higher level of female involvement in such activity in the most recent era. Some forms of illegal (and deviant) activity have always involved females to a significant degree, with prostitution and sex work as primary examples. Feminist criminologists who have explored female involvement in sex work have not been unified in their characterization of such female offenders—are they exploited victims or liberated women?—and indeed, no single feminist criminological perspective is uniformly adopted. The focus of criminological research historically has been overwhelmingly directed toward male offenders.

The feminist movement, since the 1970s, has had a significant impact on a wide range of cultural attitudes and social policies, and feminist criminologists have played some role in promoting policies, such as the reform of rape laws to diminish the further victimization of rape victims and the recognition of sexual harassment as a significant offense. They have also played a noteworthy role in the evaluation of the actual effects of such policy initiatives.

Left Realism

This perspective emerged largely in Great Britain and Canada in the period after 1985 as a response to the perceived analytical and practical deficiencies of radical criminology, especially in its neo-Marxist form. Jock Young in

England and Walter DeKeseredy in Canada have been among the primary promoters of this perspective. Left realists realized that right-wingers were able to largely preempt the crime issue, because the fear of street crime is pervasive and intense and typically has more immediacy than fear of elite crime. Radicals who either ignore street crime or, even worse, are seen as romanticizing street criminals lose all credibility in the eyes of their largest potential constituency. Furthermore, traditional radical criminology does not attend to the fact that the principal victims of street crime are disadvantaged members of society and that conventional crime persists in noncapitalist societies. Left realists also reject one-dimensional interpretations of state crackdowns on street crime that characterize it exclusively as repression. However, left realists vehemently deny that their work leads in the same direction as right realists, and they differ from right realists in many ways: They prioritize social justice over order; reject biogenetic, individualistic explanations of criminality and emphasize structural factors; are not positivistic, insofar as they are concerned with social meaning of crime as well as criminal behavior and the links between lawmaking and lawbreaking; and they are acutely aware of the limitations of coercive intervention and are more likely to stress informal control. Left realist criminology insists on attending to the community as well as the state, the victim as well as the offender. It argues that some traditional criminological research methods can be used to generate research that can serve progressive objectives. Some left realists have focused on the crimes of powerful corporations. Here, however, the tendency has been to call for more regulation and tougher sanctions against lawbreakers who cause immense, demonstrable harm but who have been able to shield themselves from criminalization due to their wealth and influence. Altogether, left realists may be said to advocate policies and practices toward both conventional and corporate crime that are realistic as well as progressive.

The preceding sections identified four principal strains of critical criminology that are quite universally recognized as such. In the following sections, several other strains that are increasingly also acknowledged to be significant strains of critical criminology are identified.

Emerging Strains of Critical Criminology

Newsmaking Criminology and Public Criminology

Karl Marx famously argued that one should not be content to explain the world; one should change it. It is an enduring complaint about many forms of academic disciplines that they are insular and self-indulgent and make no measurable impact on the “real” world. Certainly they do not contribute to the alleviation of human suffering, in its various manifestations. Critical criminologists may be especially sensitive to

this type of critique and the need for some form of praxis whereby “real-world” differences are effected. Newsmaking criminology, as originally promoted by Gregg Barak, calls for direct engagement by critical criminologists with a broad public constituency through actively seeking out opportunities to put across a critical criminological perspective on issues of crime and criminal justice in mass media outlets. Increasingly, of course, it is recognized that efforts to reach a broader audience—especially a younger audience—must involve the Internet. In a somewhat parallel vein, Elliott Currie, among others, has recently promoted a *public criminology* with a critical dimension. Too much of criminology—including some of critical criminology—is regarded as narrowly focused or adopting terminology and forms of analysis that are comprehensible to only a small number of other (like-minded) criminologists instead of addressing pressing substantive issues such as harmful present criminal justice policies in forms—and forums—capable of reaching a broader public. Such initiatives raise the question of whether newsmaking or public criminologists can realistically expect to inform and engage a public massively resistant to such engagement and largely distracted by a formidable culture of entertainment.

Cultural Criminology

The recognition of the profoundly stylistic and symbolic dimension of certain forms of lawbreaking and deviant behavior has been a primary focus of cultural criminology. This critical criminological approach, pioneered by Jeff Ferrell, among others, has sought to provide rich or “thick” descriptions of people who live at the margins of the conventional social order, including, among others, drug users, graffiti writers, motorcyclists, and skydivers, drawing on an ethnographic approach that often involves direct participant observation as well as on autobiographical and journalistic accounts. The “crimes of style” that cultural criminology addresses are best understood in relation to the contested political environment within which they occur and as representations of cultural values that challenge, on various levels, the dominant cultural value system of contemporary society. Some critics have complained that cultural criminologists overempathize with the social deviants and “outlaws” about whom they write and that they fail to adequately appreciate the perspective and legitimate concerns of the members of society charged with addressing their activities. However, cultural criminology provides us with a colorful and multilayered appreciation of a range of marginalized members of society.

Convict Criminology

Prison convicts have been a significant focus of criminological concern from the outset. However, a recently established *convict criminology* puts forth the notion—quite parallel to claims made by gender- and race-focused

criminological perspectives—that the authentic experience of prison convicts often fails to fully emerge from the studies of conventional or *managerial* criminology. Furthermore, people who have served time in prison also offer a unique perspective on correctional reforms. A number of former convicts have become professors of criminology and criminal justice and have published books and articles on the prison experience. At least some of them have become a key part of the development of convict criminology. Their insider knowledge of the world of prisons makes them uniquely qualified to conduct ethnographic studies of prison life. They might also be said to have an extra measure of credibility in claims that existing policies of incarcerating huge numbers of nonviolent offenders, including many low-level drug offenders, and then subjecting them to demeaning and counterproductive conditions, do not work and should be abandoned. Convict criminology accordingly adopts core themes of critical criminology in calling for understanding crime and its control from the bottom up and in exposing the profound limitations of public policies imposed on a profoundly disadvantaged segment of the population.

Critical Race Criminology

If gender has been one significant variable in relation to crime and criminal justice, race has certainly been another. Accordingly, some critical criminologists have focused on both the historical role of racism in producing discriminatory treatment toward people of color in all aspects of crime and criminal justice as well as the role that enduring (if less manifestly obvious) forms of racism continue to play in promoting images of criminals and policies and practices in processing criminal offenders. It is well-known that racial minorities—and African American men in particular—are greatly overrepresented in the correctional system, and some of the work of critical race criminologists is directed toward demonstrating how this overrepresentation not only reflects embedded racist elements of our criminal law and criminal justice system but also contributes toward supporting a lucrative prison industry.

Beyond the strains of critical criminology discussed earlier, there are some additional emerging strains or proposed strains, although it remains to be seen whether they will be widely embraced and further expanded. *Queer criminology* explores the manifestations of homophobia in the realm of crime and criminal justice. *Green criminology* exposes and analyzes social practices and policies that are environmentally harmful. *Countercultural criminology* calls for addressing the “colonial” issues largely neglected in mainstream criminology and critical criminology. Certainly there is some critical criminological work coming out of developing countries today addressing the crime and crime control issues afflicting these countries and, more typically now, by drawing on indigenous intellectual traditions, as opposed to simply applying Western (Occidental) theories

and frameworks. *Biocritical criminology* is a call for critical criminologists to acknowledge that genes play some role in at least certain forms of criminal behavior, and a cooperative endeavor between criminologists with a biosocial orientation and critical criminologists might disentangle the relative contributions of the political economy, the societal environment, and biogenetic factors in the emergence of criminal behavior. *Species-related critical criminology* calls for recognition that animals (or species other than human) are victims of a broad range of crimes by social institutions and specific human beings.

Summary

It should be obvious from the preceding discussion that critical criminology is an exceptionally diverse enterprise. It is also characterized by some measurable internal criticism, for example, from those who remain committed to the original utopian project of radical criminology and a fundamental transformation of society and from those who have adopted a more limited, practical approach of exposing limitations of mainstream criminological approaches to crime and criminal justice and promoting piecemeal reforms. Such pluralism is perhaps inevitable in critical criminology, and ideally the diverse strands of this enterprise complement and reinforce each other.

The Substantive Concerns of Critical Criminology

Critical criminologists have attended to conventional forms of criminal activity—such as street crime and drug trafficking—but when they have done so, they have been especially concerned with demonstrating how these conventional forms of criminality are best understood in relation to the attributes of a capitalist political economy. Accordingly, the approach of critical criminologists to such forms of crime differs from that of mainstream criminology, which is more likely to focus on individual attributes, rational calculations and routine activities, situational factors, and the more immediate environment.

The study of domestic violence and rape, with a range of studies exploring the cultural forces that both promote such violence and that have led to its past marginalization by the criminal justice system, has been a major preoccupation of feminist and left-realist criminologists. The role of “masculinities” in such crimes, as well as in various forms of street crime, has been explored as well. In recognition of the expanded involvement of females in conventional forms of crime—as one outcome of various liberating forces within society—some critical criminologists have addressed such matters as female gang members and their involvement in gang violence, with special emphasis on disparities of power.

Some critical criminologists have focused on newer forms of crime, such as hate crimes, which have a controversial

status within the larger society. The challenge here is to demonstrate why such crimes have demonstrably harmful consequences that warrant recognition of their special character and why they should not be viewed as protected by the traditional liberal commitment to freedom of speech. Ethnic, racial, and sexual minority groups have been among the favored targets of such crime, and immigrant communities remain especially vulnerable.

Critical criminologists have been especially receptive to the claim that the most significant forms of crime are those committed by the powerful, not the powerless. Accordingly, some critical criminologists have taken up Sutherland’s call to attend to white-collar crime, with special emphasis on the crimes of large, powerful corporations. Within capitalist societies, corporations operate in an environment of unequal distribution of market power and relentless pressure to increase profit or growth, and they violate laws when the potential benefits of doing so are regarded as outweighing the potential costs. State regulation of corporate activity is significantly inhibited by the disproportionate influence of corporations in making and administering laws and by the states’ need to foster capital accumulation. Friedrich Engels—the collaborator of Marx—put forth the claim in the 19th century that the ownership class was guilty of murder because it is fully aware that workers in factories and mines will die violent, premature deaths due to unsafe conditions. Some critical criminologists today focus on the persistence of “safety crimes” in the workplace and the ongoing relative neglect of such crimes by most criminologists. Others have addressed environmental crimes carried out in the interest of maximizing profit, and it seems likely that concern over such crimes will intensify in the future. The production and distribution of a wide range of harmful products, from defective transportation vehicles to unsafe pharmaceuticals to genetically modified foods, are ongoing matters of interest in this realm.

Critical criminologists are responsible for introducing the concept of state–corporate crime into the literature, that is, demonstrable (often large-scale) harms that occur as a consequence of cooperative activity between state agencies and corporations. The complicity of various major corporations, such as I. G. Farben with the Nazi state, in relation to the Holocaust, is a classic case of state–corporate crime, but there are many other such cases in the world today.

The term *crimes of globalization* has been applied to the many forms of harm that occur in developing countries as a consequence of the policies and practices of such international financial institutions as the World Bank, the International Monetary Fund, and the World Trade Organization. From 1999 on, major protests in Seattle, Washington; Washington, D.C.; and other places directed at these institutional financial institutions demonstrate that outrage at some of their activities is quite widely diffused.

In 1988, Chambliss, whose work had a significant influence on multiple generations of critical criminologists,

was serving as president of the American Society of Criminology. Radical and critical criminologists have not been elected typically to leadership positions in professional criminological associations, although there have been a few other cases of such leadership. In his presidential address, Chambliss focused on state-organized crime. Just as Sutherland almost 50 years earlier had urged his fellow criminologists to attend to the hitherto-neglected topic of white-collar crime, Chambliss in a similar vein was encouraging more criminological attention to the crimes of states, which had been almost totally ignored by criminologists. In the intervening years a growing number of critical criminologists have addressed a wide range of state-organized forms of crime, including crimes of the nuclear state, crimes of war, and the crime of genocide. A resurgent form of militarism in societies such as the United States has also been a focus of the attention of some critical criminologists.

Some critical criminologists have focused on the many different ways that the principal agents of social control—including the police, the courts, and the prisons—reflect the values and interests of the privileged and powerful strata of society and all too often realized repressive and counterproductive outcomes. Critical criminologists are concerned with identifying forms of social control that are cooperative and constructive. For some critical criminologists, the death penalty—almost uniquely retained by the United States among developed nations—is a worthy focus of attention, insofar as it brings into especially sharp relief the inherent injustices perpetrated by the existing system.

Finally, at least some critical criminologists have directed some attention to matters principally of interest to academics and researchers in relation to their professional activities. Accordingly, they have addressed some of the ethical issues that arise in relation to criminological research, with special attention to the corrupting influence of corporate and governmental funding of such research. Other critical criminologists have addressed challenges that arise in a pedagogical context: on the one hand, exposing students who are often largely either relatively conservative or apolitical in their outlook to a progressive perspective, without alienating or inspiring active hostility from such students, and on the other hand, providing programs such as criminal justice, conforming with expectations that students be prepared for careers as agents of the criminal justice system while at the same time addressing the repressive and inequitable character of such a system.

Conclusion

Critical criminology has in one sense tended to reflect the dominant focus of mainstream criminology on crime and its control within a particular nation; however, going forward in the 21st century, there is an increasing recognition that many of the most significant forms of crimes occur in the international sphere, cross borders, and can only be properly understood—and controlled—within the context

of the forces of globalization. Accordingly, a growing number of critical criminologists have addressed such matters as collapsed states within a global economy, harms emanating out of the policies of such international financial institutions as the World Bank, the crimes of multinational corporations, trafficking of human beings across borders and sex tourism in a globalized world, the treatment of new waves of immigrants and refugees, international terrorism, the spread of militarism, preemptive wars as a form of state crime, transnational policing, international war crime tribunals, and transitional justice.

Although at least some of these topics have been occasionally addressed by mainstream criminologists, critical criminologists highlight the central role of imbalances of power in all of these realms. Altogether, critical criminologists going forward are increasingly likely to take into account the expanded globalized context, regardless of their specialized interest or focus.

On the one hand, critical criminologists fully recognize the immense power of corporate interests—and other privileged interests and constituencies—to shape public consciousness in a manner that is supportive of a capitalist political economy and the broad popular culture that is one of its key products. The Italian neo-Marxist theorist Antonio Gramsci famously advanced the notion of *hegemony* to capture this capacity of privileged interests to influence public consciousness in fundamental ways. On the other hand, many critical criminologists are also, on some level, both somewhat puzzled and disappointed that the critical perspective on the political economy has failed to gain more traction with a wider public constituency by now. What is the future destiny of critical criminology? The most pessimistic projection would be that conventional and mainstream perspectives will succeed in rendering critical criminology increasingly marginalized. In a more moderate projection, critical criminology will continue to be a conspicuous and measurably influential alternative to dominant forms of criminological theory and analysis, although it will also continue to be overshadowed by mainstream criminology. In the most optimistic projection, the influence and impact of critical criminology will increase exponentially in the years ahead, perhaps at some point even coming to overshadow mainstream forms of analysis. For some version of this last scenario to be realized, perhaps a “perfect storm” of both objective and subjective conditions (to follow Marx’s own celebrated thesis) must take place: On the objective side, one would have the intensification of some fundamental forms of social inequality and injustices, and accordingly of human suffering. On the subjective side, one would have a more enlightened and autonomous “critical mass” of the citizenry that comes to recognize both the failures and the injustices of existing arrangements and policies within the political economy, and the inherent persuasiveness of critical perspectives, including that of critical criminology. In a world where inequalities of power and wealth have intensified recently in certain significant respects, it seems more likely than not that critical criminology will continue

to play a prominent role in making sense of crime and its control and the promotion of alternative policies for addressing the enduring problem of crime.

CULTURAL CRIMINOLOGY

JEFF FERRELL

Texas Christian University

Over the past two decades, cultural criminology has emerged as a distinctive perspective on crime and crime control. As the name suggests, *cultural criminology* emphasizes the role of *culture*—that is, shared styles and symbols, subcultures of crime, mass media dynamics, and related factors—in shaping the nature of criminals, criminal actions, and even criminal justice. Cultural criminologists contend that these factors must be considered if we are to understand crime in any of its forms: as a moment of victimization in the street or in the home, as a collective or group activity, or as a social issue of concern to politicians or the public.

Cultural criminologists, for example, study the ways in which criminal subcultures recruit and retain members through secretive shared experiences, distinctive styles of clothing, and exclusive ways of talking. They examine the ways in which police officers display their power and authority through police uniforms and special language and the ways in which the authority of criminal justice is symbolized in the court or the prison. Cultural criminologists often focus on media technology and the mass media and the process by which television shows, popular films, and newspaper reports communicate particular images of crime, criminals, and criminal justice and so affect public perceptions of them. Similarly, they look at the ways in which politicians and lawmakers define some crimes as more important than others and then encode these definitions in

laws and enforcement policies. This broad focus on culture and communication, cultural criminologists argue, allows scholars, students, and the public to develop a deeper and more critical understanding of crime and criminal justice. From this view, the subject matter of criminology cannot simply be criminals and what they do; instead, it must include the ways in which crime is *perceived* by others; the particular *meanings* that crime comes to have for criminals, victims, crime control agents, and everyday citizens; and the consequences of these meanings and perceptions for criminal activities, crime control policies, and even the politics of contemporary society.

It is significant that cultural criminologists intend this perspective to expand the subject matter and analytic approach of conventional criminology—but they also intend for cultural criminology to provide a distinct alternative to conventional criminology and at times to directly confront what they see as its current weaknesses and limitations. As already suggested, this divergence between cultural criminology and more conventional forms of criminology is partly one of subject matter; over the past few decades, conventional criminology has largely dismissed from analysis the very components of social life—media, style, symbolism, meaning—that cultural criminologists argue are essential for a fully developed criminology. In this sense, cultural criminologists push to incorporate these elements—or, as discussed in this chapter, reincorporate them—into criminology.

But, as we will also see, the tension between cultural criminology and conventional criminological perspectives runs deeper than simply subject matter. Cultural criminologists contend that many of the more popular contemporary criminological theories are inadequate for explaining crime precisely because they exclude any understanding of culture, communication, and meaning. They likewise argue that the most widely used research methods in conventional criminology are designed in such a way that they inevitably ignore the most important features of crime, culture, and social life. And they point out that many of these current failings are the result of conventional criminology's overidentification with criminal justice, and its overreliance on governmental grants and legalistic definitions of crime. In this sense, cultural criminology is designed not only to study crime, but to study and critique the taken-for-granted practices of contemporary criminology.

Theory

Cultural criminology has developed from a synthesis of two primary theoretical orientations, one largely British, the other primarily American. In the 1970s, scholars associated with the Birmingham School of cultural studies, the National Deviancy Conference, and the "new criminology" in Great Britain (S. Cohen, 1972; Taylor, Walton, & Young, 1973) began to explore the distinctive cultural dynamics through which power was exercised and maintained. In this context they also examined the ideological dimensions of crime and crime control—that is, the ways in which crime issues and concerns often tapped into larger political agendas—and they linked all of this to emerging patterns of social and economic inequality. Reconceptualizing the nature of social control and resistance to it, these scholars documented the cultural practices associated with social class, investigated leisure worlds and illicit subcultures as sites of stylized defiance to authority, and recorded the mediated campaigns and ideologies essential to social and legal control. In this way they began to conceptualize some of the many links between cultural and criminal processes.

During roughly this same time, a second starting point for cultural criminology was emerging among American sociologists and criminologists who used symbolic interactionist theory and labeling theory in their study of crime and deviance (Becker, 1963). These scholars argued that the nature and consequences of crime were not inherent to an individual criminal act; instead, they were largely determined by others' reactions to an act or person—that is, by others' perceptions and by the meanings they attributed to the act or individual. Killing another person, for example, can mean many things to many people: murder, self-defense, heroism, or insanity. Likewise, politicians or police officers or the family of the victim can subsequently make the killing into a symbol of something else: the

decline in morality, the dangers of guns, or the need for stronger laws. The social reality of crime—fears about it, models for confronting it, social harms engendered by it, even the visceral experience of it as perpetrator or victim—is therefore seen to be part of an ongoing cultural and political process. Like their counterparts in Great Britain, American symbolic interactionists and labeling theorists were beginning to link crime, culture, and power. Significantly, they were also beginning to document these linkages through ethnographic research inside the worlds of drug users, pool hustlers, and other "outsiders" (Becker, 1963), producing a series of case studies that revealed how criminals and anti-crime crusaders alike constructed meaning and negotiated symbolic communication.

In the following decades, these two orientations co-evolved, with British cultural theorists and "new criminologists" providing American scholars with sophisticated theoretical critiques of ideological control and American interactionists offering ethnographic inspiration to British scholars. In the mid-1990s, the two orientations were synthesized for the first time into a distinct "cultural criminology" (Ferrell & Sanders, 1995) that, while building primarily on these twin foundations, also integrated the work of subcultural researchers, postmodern theorists, cultural geographers, and progressive political theorists. Exploring further the symbolic components of crime, this new cultural criminology focused especially on two dynamics: (1) the ways in which criminal enterprises incorporate cultural components of style, dress, and language and (2) the ways in which cultural enterprises such as art and music are often criminalized by legal authorities and moral entrepreneurs (Becker, 1963). Honoring the informal history of trans-Atlantic co-evolution, this more formalized cultural criminology has also continued to integrate scholarly work from the United States, Great Britain, and beyond.

Cultural criminologists today use a variety of theoretical models that incorporate and expand on these intellectual orientations. Among the more influential of these is the concept of *edgework*, as developed by Steve Lyng (1990, 2005), Jeff Ferrell (1996), and others (Ferrell, Milovanovic, & Lyng, 2001). These theorists argue that acts of extreme and often illegal risk taking—graffiti writing, street racing, BASE (building, antenna, span, earth) jumping (i.e., jumping off a fixed object with a parachute) from cliffs or buildings—can best be understood not as moments of out-of-control self-destruction but as situations in which participants reclaim a sense of self through an exhilarating mix of risk and skill. This sort of edgework allows participants to develop the sort of finely crafted skills that are today often absent from the tedium of daily life and daily work, and it forces them to test these skills in meaningful situations that matter profoundly. This mix of skill and risk in turn spirals participants closer to the edge; after all, the more polished one's skills as a street racer or graffiti writer, the more risk one can take—and the more risk one takes, the more polished those skills must become.

In this way, cultural criminologists attempt to go inside what Jack Katz (1988) called the immediate *seductions of crime*—that is, inside its experiential meaning and allure for participants—while also seeing this edgework experience as a response to larger, dehumanizing social forces. The edgework concept also helps explain another, ironic dynamic between crime and criminal justice. Given that edgework generates a seductive adrenalin rush as participants mix skill and risk, aggressive law enforcement strategies designed to stop illegal edgework often serve only to heighten the risk and so to force the development of further skills—thereby amplifying the very experience that participants seek and legal authorities seek to prevent.

Two other cultural criminological theories likewise address the links among experience, emotion, perception, and larger social conditions. Mike Presdee (2000) posited that contemporary crimes such as drug taking, gang rituals, arson, and joyriding in stolen cars can be understood through a theory of *carnival*. Carnival has in many human societies historically been a time of dangerous excess, ridicule, and ritualized vulgarity; yet since it was ritualized, and so confined to particular periods and places, it also served to contain dangerous desires, to serve as a sort of temporary emotional safety valve after which normalcy was restored. Now, Presdee argued, carnival has been for the most part destroyed, outlawed in some societies and converted into legally regulated and commercialized spectacles in others. As a result, some remnants of carnival are now bought, sold, and consumed in the form of sado-masochistic pornography or degrading reality television shows, but others are enacted as crime, all the more dangerous because now cut loose from their containment within a community ritual.

Jock Young (1999) widened this focus in addressing contemporary economic and cultural dynamics and their connections to criminality. His theory of *exclusion/inclusion* notes that contemporary society is defined by the increasing economic and legal exclusion of large portions of the population from “respectable,” mainstream society. The loss of millions of jobs, the prevalence of low-wage work, the economic decay of many inner cities, the mass incarceration rates in the United States—all serve to exclude many among the poor, ethnic minorities, and even the formerly middle class from the comforts of mainstream society. Yet at the same time, these and other groups tend to be increasingly culturally included; through the power of the mass media and mass advertising, they learn to want the same consumer goods and symbols of lifestyle success as do others. Increasing levels of frustration, resentment, insecurity, and humiliation are the result—and with them, Young pointed out, crimes of retaliation and frustration as well. Echoing Robert K. Merton’s (1938) famous formulation of adaptations to socially induced strain, Young argued that this heightened strain between economic exclusion and cultural inclusion helps us understand all manner of crimes, from those of passion to those of economic gain.

A final theoretical model focuses especially on the interplay of the media, crime, and criminal justice in contemporary society. Ferrell, Hayward, and Young’s (2008) theory of *media loops and spirals* argues that we are now well beyond simple questions of how accurately the media report on crime or whether media images cause copycat crimes. Instead, they argued, everyday life is today so saturated with media technology and media images that a clear distinction between an event and its mediated image seldom exists, and so criminologists are confronted by a looping effect in which crime and the image of crime circle back on one another. When gang members stage violent assaults so as to record them and post them on the Web, when reality television shows entrap their participants in actual assaults and arrest, when police officers alter their street enforcement strategies because of their own police car cameras or the presence of news cameras, then crime and media have become inherently entangled. Moreover, these loops often reproduce themselves over time, spawning an ongoing spiral of crime, criminal justice, and media. Videotapes of police activities, for example, often become the basis for later court cases, which are then covered in local or national media; similarly, images of criminality often function over time as legal evidence, marketed entertainment, and fodder for news reporting. Because of this, cultural criminologists argue, any useful criminology of day-to-day crime and violence must also be a cultural criminology of media and representation.

Methods

Cultural criminology’s theoretical orientations intertwine with its methods of research. As already seen, cultural criminology and its various theories focus on the meaning of crime, as constructed in particular situations and more generally; on the emotions and experiences that animate crime and criminal justice; and on the role of mediated representation and cultural symbolism in shaping perceptions of crime and criminals. To conduct research that is informed by these theories, then, cultural criminologists need methods that can get them inside particular criminal situations and experiences and that can attune them to emotion, meaning, and symbolism. They also need methods that can penetrate the dynamics of media technology and the mass media and that can catch something of the loops and spirals that entangle crime and its image. Cultural criminologists argue, though, that the research methods conventionally used by criminologists are ill-suited to this task, and so cultural criminologists regularly adopt alternative methods of research.

From the view of cultural criminology, for example, survey research and the statistical analysis of survey results—the most widely used methods in conventional criminology—preclude by their very design any deep engagement with meaning, emotion, and the social processes by which meaning and emotion are generated. Such methods force the

complexities of human experience and emotion into simplistic choices prearranged by the researcher and so reduce research participants to carefully controlled categories of counting and cross-tabulation. Such methods remove the researcher from the people and situations to be studied, creating a sort of abstract, long-distance research that excludes essential dynamics of crime and justice—ambiguity, surprise, anger—from the process of criminological research (Kane, 2004). Worse yet, cultural criminologists argue, such methods are often used precisely because they do produce safe findings and abstract statistics in the service of political agencies or criminal justice organizations, thereby forfeiting the critical, independent scholarship that cultural criminologists see as necessary for good criminological research and analysis.

Instead of relying on such methods, then, cultural criminologists often turn to *ethnography*: long-term, in-depth field research with the people to be studied.

Cultural criminologists who are deeply immersed in the lives of criminals, crime victims, or police officers can become part of the process by which such people make meaning and can witness the ways in which they make sense of their experiences through symbolic codes and shared language. Sharing with them their situations and experiences, and vulnerable to their tragedies and triumphs, cultural criminologists likewise learn something of the emotions that course through their experiences of crime, victimization, and criminal justice.

For cultural criminologists, this goal of gaining deep cultural and emotional knowledge is embodied in the concept of *criminological verstehen*. As developed by sociologist Max Weber, the concept of *verstehen* denotes the subjective or appreciative understanding of others' actions and motivations—a deeply felt understanding essential for fully comprehending their lives. Notice that here the methods of cultural criminology in fact oppose and reverse the methods of conventional criminology. Instead of the “objectivity” of preset surveys and statistical analysis producing accurate research results, as is commonly assumed, it is in fact *emotional subjectivity* that ensures accuracy in research; without it, the researcher may observe an event or elicit information but will gain little understanding of its meaning or consequences for the actors involved.

A similar difference can be seen in cultural criminologists' approach to media research. Conventional criminologists most often study media and crime by using the method of *content analysis*—the measuring of static content categories within media texts. Cultural criminologists argue, though, that the fluid interplay among media, crime, and criminal justice cannot be captured in quantitative summaries of textual word frequency or source type. Numeric summaries of discrete textual categories miss the larger aesthetic within which a text takes shape and ignore the structural frames that shape a text's flow of meaning. Moreover, content analysis is regularly used with the intent of objectively proving the degree of divergence between the

“real” nature of a crime issue and a “biased” media representation of it—but this approach misses the more complex dynamic of media loops and spirals and the multiplicity of audiences and interpretations that will confound the real and the representational as a crime issue runs its course.

In place of traditional content analysis, then, cultural criminologists use two alternative methods. The first is David Altheide's (1987) method of *ethnographic content analysis*, an approach that conceptualizes such analysis as a search for meaning and a process of intellectual give-and-take between researcher and research participant. This method is designed to produce deep involvement with the text, such that the researcher develops a deep account of the text and its meanings. It is also designed to approach the media text not as a single entity but as an emergent cultural process incorporating various media, political, and cultural dynamics. Like conventional content analysis, then, this method allows researchers to identify and analyze textual patterns, but it also taps into the fluid, looping media that increasingly define crime and justice. A second alternative approach goes a step further and in fact returns us to ethnography: field work with criminals, criminal justice workers, or others as they go about interacting with the mass media, developing images of their own lives, or even inventing their own alternative media (Snyder, 2009).

Applications

The cultural criminological perspective has been applied to a range of subject areas within criminology; put differently, cultural criminologists have investigated the dynamics of symbolism, meaning, and representation amid a variety of criminal and criminal justice situations.

Some of the best-known work in cultural criminology has used ethnographic methods to explore illicit subcultures and their interactions with legal authorities and the media. This close attention to particular subcultural dynamics has allowed cultural criminologists to confront media and criminal justice stereotypes of these subcultures and to deepen scholarly knowledge of them. Ferrell (1996, 2001, 2006), for example, has conducted long-term participatory ethnographies of three urban subcultures: (1) hip hop graffiti writers, (2) street-level political activists, and (3) trash scroungers. In each case, his findings have served to humanize the members of the subcultures, to reveal the ways in which they engage in meaningful collective action, and to challenge the validity of aggressive criminal justice campaigns against them. Alternatively, Mark Hamm's (1997, 2002) long-term ethnographic research among various subcultures associated with extremist, right-wing terrorism has revealed hidden dimensions of their strategies and ideologies and so has helped strengthen legal efforts to contain them. From the perspective of cultural criminologists, then, a deep understanding of a subculture's values and practices can help shape more appropriate public and

legal responses to them, whether those responses eventually become more tolerant or more condemnatory. In a similar fashion, other researchers have used cultural criminological perspectives in the in-depth, ethnographic study of illegal street racers, youthful brawlers, police officers, immigrant communities, drug users, and youth gangs.

As Ferrell's three ethnographies of urban subcultures suggest, cultural criminological models have been found to be especially applicable to the swirl of subcultures, images, and interactions that animate urban life and urban criminality. Keith Hayward (2004) in particular has developed a comprehensive cultural criminological analysis of urban crime and urban social control in the context of consumer culture. Drawing on and revitalizing long-standing traditions of criminological theory and urban scholarship, Hayward has revealed the many ways in which consumer culture has come to penetrate urban life and urban spaces, intertwining with the practice of both legal control and crime and in many ways defining the city itself. With the cultural criminologist's eye for situated meaning and symbolic interaction, he has also documented the existence of two different sorts of city life within large urban areas: on the one hand, the regulated, rationalized city of urban planners and legal authorities, and on the other hand, the ambiguous, spontaneous city of underground economies and illicit urban subcultures.

A variety of cultural criminological studies have explored the interplay of crime, media, and representation. Many of these studies have investigated the complex dynamics by which the mass media construct a particular crime concern or criminal justice issue and the ways in which these media dynamics in turn intertwine with public perceptions and criminal justice policy. In this way, cultural criminologists have studied, for example, mass media campaigns surrounding "three strikes and you're out" sentencing policy and reform-minded "get smart on crime" movements, and they have analyzed media representations of child sexual abuse, regional drug use, female criminals, and popular music controversies. Cultural criminological perspectives have also been applied to a wide range of popular media forms, including heavy metal music, bluegrass music, cartoons and comic books, television shows (e.g., *CSI* [Crime Scene Investigation]), and films on prisons and policing. As suggested by the theory of media loops and spirals, though, cultural criminologists have also explored media and representation outside the conventional boundaries of the mass media, focusing especially on the ways in which mediated representation, crime, and criminal subcultures are increasingly interwoven. Cultural criminologists have, for example, carefully studied the cultural symbolism of the shrines constructed in memory of the September 11, 2001, attacks on the United States and the symbolic reminders offered by roadside shrines to victims of automotive tragedy. They have also documented the ways in which graffiti, corporate advertising, and political messages are confused within shared urban spaces and the ways in

which criminal subcultures are increasingly defined by their ability to invent their own media and so to communicate beyond any one locality.

Comparisons

As already noted, cultural criminologists often pose their work as a distinct alternative to the practice of conventional criminology, and even as a direct critique of it. Given this built-in sense that cultural criminology exists in contrast to more mainstream criminological approaches, two comparisons are especially worth exploring: (1) the comparison between cultural criminology and some of the more conventional criminological perspectives and (2) the comparison between cultural criminology and other alternative approaches that, like cultural criminology, seek to distinguish themselves from mainstream criminology.

Regarding the first of these comparisons, one aspect has already been noted: the distinction between conventional criminological research methods such as survey research and statistical analysis and cultural criminological methods of ethnography and in-depth field research. This choice of methodological orientations, though, derives from a still deeper difference. The use of survey research and statistical analysis is based on a general assumption that there exists an external and objective social reality to be studied; this objective reality can therefore be tapped into through survey questions, and its meaning can be *deduced* through statistical analysis and comparison. According to this view, for example, particular rates of crime commission or crime victimization exist in the social world; their frequency can be measured, and their meaning for those involved can be ascertained by compiling survey responses or noting statistical correlations between one act and another. From the view of cultural criminologists, though, the reality of crime and victimization is never objective or self-evident but always in the process of being constructed, interpreted, and contested—and, following the insights of labeling theory, this process is inevitably ongoing. For cultural criminologists, then, the subject matter of criminology is not the objective, "obvious," and measurable reality of crime or criminal justice but rather the complex cultural process by which this reality is constructed and made meaningful. In this sense, for example, the rate of domestic violence is not an objective fact that can be measured but instead a shifting reality affected by how domestic couples define violence and how they choose to report it to the police, police officers' subsequent discretion in responding to domestic violence calls, varying legal statutes regarding domestic violence, the greater or lesser visibility of domestic violence in the media—and, moreover, the interaction among all these factors. Because of this, cultural criminologists must have methods such as ethnography or ethnographic content analysis that can immerse them in ongoing, interactional process by which

criminals and crime victims, police officers, and news reporters collectively make sense of crime.

It is significant that these different assumptions about the nature of social reality show up not only in the original research that criminologists undertake but also in their approach to information produced by governmental agencies or the criminal justice system. Many mainstream criminologists rely on governmental agency statistics as a relatively accurate measurement of objectively knowable facts, such as the distribution of crime occurrences, increases or decreases in crime rates, or the prevalence of particular crimes in particular areas. Cultural criminologists are, on the other hand, more likely to see such statistics as reflecting not the objective, external reality of crime, but rather the internal workings and biases of the governmental agencies themselves. Because of this, another key difference arises: Instead of relying on governmental statistics as the basis for criminological research into crime or victimization, cultural criminologists argue that these statistics should be a *focus* of criminological research—that is, should themselves be studied by criminologists—for what they can tell us about criminal justice and its political and legal limitations.

The issue of gangs and gang crime provides a particularly instructive example. As part of governmental anti-gang policy and the “war on gangs,” the U.S. Department of Justice Office of Juvenile Justice and Delinquency Prevention conducts a National Youth Gang Survey so as to measure the number of gangs and gang members in the United States, as well as trends in gang membership and activities. The survey seemingly produces precise measurements of gangs numbers and gang members—but in fact the survey, which self-admittedly provides no guidelines or definitions as to what might constitute a gang member or a gang crime, is sent only to law enforcement agencies, where it is then completed on the basis of an unknown mix of personal recollections and/or official records. Cultural criminologists argue that such supposedly “objective” research procedures tell us little or nothing about gangs and their cultures—careful ethnography is needed to gain this knowledge (Kontos, Brotherton, & Barrios, 2003)—but they do tell us much about the inadequate and inherently biased foundations for governmental anti-crime policy.

Cultural criminology’s preferred research methods, and its perspective on more conventional research methods, in this way bolster its critical approach to both mainstream criminology and the criminal justice system. A similar sort of critical stance becomes apparent when cultural criminological theories are compared with some of the more popular theories in mainstream criminology. Recall that cultural criminological theories generally focus on the subtleties of symbolism and representation, on the shared human emotions that animate crime, and on the powerful cultural forces that shape the meaning and importance of crime. In contrast, for example, rational choice theory, which is widely used in mainstream criminology, systematically

denies or ignores these factors in its attempts to explain crime and criminality. According to rational choice theory, criminal events unfold along a linear sequence of rational decision making, with criminal perpetrators inevitably seeking through this rational decision making to maximize their own benefits. Rational choice theorists further argue that this sequence of choices as to preparation, target selection, and escape remains rational even if the perpetrator is drunk, drugged, or in a hurried panic. Cultural criminologists counter that this theoretical model ignores the highly charged emotions that often explode in criminal events and that it also ignores the ambiguous, contentious cultural process by which crime comes to have meaning and significance in society. Given this, cultural criminologists also critique rational choice theory for being more a simplistic justification for particular crime control campaigns (e.g., target hardening, increasing security for a specific location or target) than an explanatory theory of crime.

Another popular mainstream criminological approach—in fact, one of the most politically popular and widely applied in criminal justice—also contrasts dramatically with cultural criminological orientations. The *broken windows model* (Wilson & Kelling, 2003) of crime causation and crime prevention posits that broken windows, graffiti, and similar public displays of neglected property and petty criminality operate as invitations to further criminality. According to the model, such displays suggest to the public and to potential criminals a lack of public concern and a failure of social control; consequently, the public begins to give up hope, criminals see signs of encouragement for further crime, and so a downward spiral of further neglect and accelerated criminality ensues. Widely adopted by politicians and criminal justice officials, the logic of the broken windows model has spawned aggressive police campaigns against small-scale quality-of-life crimes, such as graffiti writing and panhandling, and police enforcement strategies that target marginalized urban populations, such as the homeless.

Cultural criminologists, on the other hand, argue that although the broken windows model may offer a convenient scholarly pretext for such criminal justice campaigns, it is wholly inadequate as a theory of crime—and moreover, that its inadequacy stems directly from its misunderstanding of key cultural criminological notions such as symbolism and meaning. From this critical view, the broken windows model simply assumes the meaning of everyday symbolism and imputes the nature of public perception instead of actually investigating or understanding them. As cultural criminologists have found in their own ethnographic research, the symbolic meanings of phenomena such as broken windows and street graffiti are far more complex than the simple invitations to further criminality or markers of failed social control that broken windows theorists assume. To the extent that the broken windows in a neighborhood building function as symbols, for example, they may symbolize any manner of activities

to any number of audiences, depending on the situation and the context: community resistance to absentee ownership, a long-standing personal grudge, errant baseballs from nearby Little League games, the failure of local code enforcement, or the illicit accommodation of the homeless. Likewise, as field researchers have shown, graffiti may symbolize a neighborhood's intergenerational history, suggest changing patterns of ethnic occupation or conflict, or even enforce a degree of community self-policing. Cultural criminologists argue that the job of the criminologist is to investigate these urban environments and to explore these various meanings and not, as with the broken windows model, to impose assumed perceptions and consequences in the service of a particular political and criminal justice agenda.

In this sort of critique, cultural criminology contrasts clearly with more mainstream criminological approaches, but it also reveals similarities with a variety of other alternative criminological perspectives. The first of these, *subcultural theory*, is widely used by both cultural criminologists and mainstream criminologists. As developed by Al Cohen (1955) and others, subcultural theory argues in general that criminologists must understand many cases of criminal behavior as being rooted in the collective reality of a criminal subculture. Because of this, criminologists must explore the particular cultural dynamics that define that subculture—codes of speech and conduct, styles of dress, shared emotions, common problems—and in turn must investigate the ways in which subcultural criminality may offer subcultural members a collective (if imperfect) solution to their shared problems. This subcultural approach clearly offers many similarities to cultural criminology; it likewise suggests a similar critique of criminological models that would ignore, or simply assume, the subtleties of meaning, symbolism, and style that shape criminal subcultures.

Other criminological approaches more explicitly share cultural criminology's critical stance toward mainstream criminology and criminal justice. *Convict criminology* has emerged primarily from scholars who were themselves once imprisoned and who have transformed their own incarceration into a critique of the criminal justice system; it uses ethnographic research and other approaches to construct a critical, cultural analysis of mass incarceration, the criminal justice policies that have produced it, and the sorts of mainstream prison research and media stereotypes that support it (Richards & Ross, 2001). Feminist criminology likewise shares with cultural criminology an analysis of the sorts of cultural assumptions that tilt both criminology and criminal justice toward privileged groups, as well as a critique of media distortions of female criminals and crime victims (Chesney-Lind & Irwin, 2008). More generally, cultural criminology, convict criminology, and feminist criminology all find common ground in that large subfield of criminology generally labeled *critical criminology*—an approach oriented toward a critical investigation of the

many ways in which power and inequality shape crime, victimization, and criminal justice.

Future Directions

Among the current trends in cultural criminology are those that are expanding the substantive range of cultural criminological analysis, especially in the direction of greater diversity and inclusivity. Originally, for example, the cultural criminological concept of edgework developed from the experiences and ethnographic research of male scholars involved in predominantly masculine forms of illicit risk taking. Now, though, the concept is increasingly being explored in the context of women's lives, with a focus on the distinctive ways in which women experience and make sense of high-risk activities. Recent research by female and male scholars has investigated women who lead BASE jumping underground, women who are members of search-and-rescue teams or whitewater rafting expeditions—even women who hone their skills so as to push the dangerous, outer boundaries of anorexia and bulimia. Similarly, cultural criminology has from its origins incorporated in equal part scholarship from both the United States and Great Britain—and now this international sensibility is widening. Cultural criminologists are now studying, for example, illegal street racing in Finland, immigration cultures and criminal law in the Netherlands, violence against Filipino women in Australia, crime discourse in Japan, the culture of Russian prisons, and the international affiliations of urban street gangs.

Cultural criminologists are also developing new methodologies designed to mirror cultural criminology's particular theoretical orientations and to resonate with the particular nature of contemporary social and cultural life. For example, ethnographic research and the quest for criminological *verstehen* have traditionally been defined by the researcher's long-term participation with the individuals being studied, on the assumption that the more time a researcher spends inside a group or situation, the more deeply he or she can understand its cultural dynamics. Although this can certainly still be the case, the rapid-fire pace of contemporary crime and culture—as embodied in virtual crime and communications, instant news and entertainment, and short-term employment—have suggested to cultural criminologists new possibilities for ethnographic research. Their theoretical models have suggested this as well; concepts such as “edgework” and the “seductions of crime,” for example, focus attention on the immediate, situated dynamics that shape criminal experiences and emotions. Consequently, cultural criminologists have developed the notion of *instant ethnography* (Ferrell et al., 2008)—a researcher's immediate and deep immersion in fleeting moments of criminality or transgression—and have begun to use the method in studying BASE jumpers and other groups.

The new notion of *liquid ethnography* (Ferrell et al., 2008) has developed from a similar rethinking of ethnographic research. Ethnography typically has focused on a single, definable group or subculture that occupies a distinct location as well. Today, though, groups and subcultures are often on the move, migrating into new locations or mixing with new groups as global economies and global migration blur distinct boundaries and identities. Moreover, as already seen with the concept of media loops and spirals, social groups are today more and more likely to be confounded with their own image, as representations of the group come to shape the group itself and to flow among alternative media, the mass media, and other institutions. Liquid ethnography, then, is a type of ethnography attuned to these circumstances—that is, it is ethnography sensitive to the dynamics of transitory communities; immersed in the ongoing interplay of images; and aware of the ambiguous, shifting nature of contemporary social life.

Using this sort of approach, cultural criminologists are now beginning to explore, for example, the ways in which urban street gangs move beyond crime to intermingle political resistance, community empowerment, and religious practice in their shifting collective identities. These cultural criminologists (Kontos et al., 2003) are also finding that global forces regularly intersect with local dynamics, with gangs embodying multiethnic identities, responding to the effects of immigration and mediated communication, and forming global alliances with other groups. Likewise, British cultural criminologists are now conducting liquid ethnographies with prostitutes, immigrants, asylum seekers, and others who are pushed to the legal margins of the global economy, and in this research they are using alternative media, such as art, photography, and street performance (O'Neill, Campbell, Hubbard, Pitcher, & Scouler, 2007). Such research allows cultural criminologists to collaborate with even the most transitory and contingent communities in defining their meaning and identity, developing the *verstehen* of shared emotional knowledge, and working toward a holistic sense of social justice.

Appropriately enough for cultural criminology, a final trajectory focuses not so much on subject matter, theory, or methodology but on representation and style. Cultural criminologists argue that issues of crime, violence, and criminal justice lie at the very heart of contemporary society and its challenges and that because of this, criminologists must find ways to disseminate their scholarship, contribute to public debate, and so help to work toward a safer and more just society. Yet conventional, mainstream criminology, they contend, is poorly equipped to meet this challenge; too often, criminologists talk and write only for each other, and they do so through dry and confusing language, needlessly abstract concepts, and impenetrable graphs and tables. As a result of this off-putting and exclusionary style, criminology's potential contribution to the larger society is lost, with criminologists and their scholarship often left on the sidelines of public debate and efforts at social progress.

Aware of this problem, and sensitive to issues of style and representation, cultural criminologists are in response increasingly experimenting with new styles of scholarship and alternative modes of communication, with the intention of making criminology more engaging for students, policymakers, and the public. In place of lengthy reports, they at times issue *manifestos*—short, sharply written texts that can communicate succinctly key ideas and issues. Instead of relying on traditional forms of academic writing, they on occasion write short stories that embody cultural criminological themes, or craft *true fiction*—that is, stories that blend a number of actual, existing crime issues into a narrative form that is more appealing to the reader. Responding to a world awash in media images, they also increasingly turn to the analysis of these images as visual documents, and they produce their own photographs, photographic collections, documentary films (Redmon, 2005), and Web sites as a way of making criminology conversant with this world.

Conclusion

Cultural criminology emphasizes the essential role of symbolism, meaning, and emotion in shaping the complex reality of crime and crime control for all involved: criminals, victims, crime control agents, politicians, the media, and the public. Cultural criminology is in this way designed to operate as a double challenge: to simplistic public assumptions about crime and criminal justice and to the theories and methods of mainstream criminology that exclude analysis of cultural forces. Today more than ever, cultural criminologists argue, there can be no useful study of crime that is not also the study of culture.

CULTURAL TRANSMISSION THEORY

MARK T. BERG

University of Missouri–St. Louis

ERIC A. STEWART

Florida State University

A core tenet of social science theory holds that normative systems, in part, produce the varied patterns of social behavior evident across and within societies. In essence, *norms* are ideas, and ideas are transmitted in social interaction. The collective manifestation of norms or shared ideas—that assume a semblance of time invariance—is *culture*. Cultural artifacts figure prominently into the logical framework of theories formulated to explain the uneven representation of violence within American society. The point of departure for these works is that neither violent crime rates nor culture are characterized by a homogeneous pattern. Indeed, cultural theories posit that variation in value systems predicts simultaneous variation in the scope and form of violent actions. Systems of shared values that do not conform to conventional culture, known as *subcultures*, explain the spatial concentration of serious and lethal violence in disadvantaged urban areas and in the southern region of the United States. Furthermore, the relative spatial permanence of violence is owed largely to the continued transmission over time of the subcultural values that sanction such behavior.

The acquisition of values favoring law violation, including violence, occurs through repeated exposure not only to unlawful behavior itself but also to the values underlying it that are entrenched in actors' social milieu. Criminologists stress that agents within an individual's social context, such as peers, the family, and neighborhood residents, convey normative protocols regarding illegal conduct. An actor's reaction to verbal threats, his or her strategy of response to

economic distress, and his or her adherence to formal legal mandates are artifacts of the normative complex that blankets the actor's daily life and that is procured through social interaction. Violence-conducive value orientations are thus effectively transmitted throughout local collectivities over time and sustained spatially.

This chapter delineates the leading perspectives in the field of criminology on subcultural processes, namely, cultural transmission. It also highlights the empirical evidence pertaining to these theories and briefly discusses the current state and future of subcultural research.

Conceptual Foundation: Representations of Subculture and Cultural Transmission in the Criminological Literature

There is not a precise or uniform definition of *subculture* in the criminological literature. For this reason it is vulnerable to critique, and the theories organized around the term are prone to misinterpretation. Subculture is, of course, a deductive artifact of culture, although it is substantively distinctive. An explicit classification of culture holds that it is the meaning humans generate and apply to their environment. This perspective permits culture to take on a variant shape across society, and it permits social consensus on values implying that, although values may differ, they do converge and assemble among groups, providing the empirical possibility of subculture. Some values are more

widespread; those that are less conventional are said to be shared by a subculture. Theoretically speaking, what signifies membership into subcultures is not simply commonality in behavior patterns but a sense of mutual cognitions pertaining to objects and actions (e.g., behaviors). To be part of a subculture necessitates that persons hold a salient and intense degree of identification with others who also make a decision to attribute similar meaning to factors in their social world. Social structural conditions, such as wider patterns of social relations, potentially function as a stimulus for group identification, serving as a salient force in collective organization and ultimately facilitating subculture formations.

By the first half of the 20th century, the study of deviance was situated in a vibrant intellectual environment, setting the stage for the development of what are now regarded as core theories of criminology. Criminologists at the time began to assume the analytical posture of *positivism*, in that they sought to discover the law-like structure governing social actions. Their objective was to develop a science of crime by way of theoretical construction. Scholars in the Chicago School of sociology applied this strategy while investigating the implications of normative shifts on behavioral patterns among rural populations negotiating the transition to urban life. Others contrasted the complex interdependence of urban growth dynamics and human behavior to the notion of symbiotic development found in the study of plant ecology. It is in this vein that the early subcultural theories of delinquency emerged from the Chicago School.

During the 1920s and 1930s, empirical research on social ecology contributed importantly to the conceptual understanding of the symbolic conditions stimulating criminal offending. On the basis of analyses of county juvenile court records, early Chicago School theorists concluded that rates of delinquency decreased precipitously with gains in distance from the city center and that rates tended to remain relatively stable across neighborhoods, despite population turnover. It was believed that such marked stability in the spatial concentration of crime was sustained by ecologically situated value systems espousing criminal behavior. This idea was ultimately incorporated as the *cultural transmission* dimension of ecological theory. It suggests that deviant subcultures act as hosts for the system of nonconventional values and are responsible for disseminating it across generations. Furthermore, structural conditions allegedly erode social control mechanisms, thereby permitting the proliferation of subcultures within neighborhoods.

Individual-level theories of social interaction were also developed around the mid-20th century with the explicit goal of explicating the symbolic aspects underlying unlawful behavior as well as its spatial persistence. The individual-level intellectual approach, which is somewhat consistent with the ecological position of cultural transmission originating in the Chicago School, posited that the stimulus for delinquency was produced in interaction with others.

Stated succinctly, this model, known as *differential association theory*, stipulates that greater exposure to persons who hold values supportive of law violation amplifies the odds that one will engage in this behavior. The propositions of the theory involve both the content of what is learned as well as the process through which it is done so. Most relevant to subcultural theory, in particular the notion of cultural transmission, is the notion that exposure to “definitions” favorable or unfavorable to law violation constitutes the content of acquired knowledge in interaction. Definitions are, in essence, ideas regarding appropriate behavior, and one is exposed to definitions favoring law violation in the same context wherein he or she is exposed to definitions regarding the appropriateness of conventional actions. Absent continued social interaction, exposure to definitions in favor of violence is probable, and hence the transmission of subculture is more likely to be sustained. There is one caveat to this position, however: It leaves little room in the process for agency—that is, the conscious decision by the actor to engage the definitions.

The Rise of the Subcultural Perspective

By the 1950s and 1960s, theorists in criminology identified limitations of the ecological and symbolic interaction variants of subcultural theory. They also sought to overcome what were perceived as the limitations of these models and to expand on their unique strengths. Where the ecological model emphasized structural sources of behavior and offered ideas about the transmission of cultural orientations, the individual-level interaction model largely overlooked structural factors, opting instead to focus more exclusively on the symbolic dimension of crime causation. During this time frame one scholar, Albert Cohen, who was working in the tradition of strain theory (although within a sub-branch known as the *reaction-formation perspective*), took issue with the fact that strain theory did not focus on the role of the group and that subcultural theories—both the ecological and interactionist brands—neglected to account for the origins of the subculture, in particular its content and its disproportionate presence in the working class.

Cohen argued that the strain model accounts for the perceived limitations of earlier subcultural models in that strain theory implicates the wider conventional culture as the force underlying delinquent behavior. More specifically, he argued that the status configuration of the wider value complex dominates all aspects of American life. By virtue of their socialization into working-class families, youth are poorly equipped to abide by the criteria of a middle-class existence (e.g., self-reliance, worldly asceticism, exercise of forethought, manners and sociability). The structural deficits of the working class also translate into cultural deficits, because the middle-class cultural standards are used by all to evaluate one’s worth. Deficits produce social psychological strain, and a reaction ensues. Similarly situated youth find common ground and ultimately band together to reject middle-class values. They

collectively devise an alternative status system that overturns the tenets of the middle-class existence. In the alternative system, respect is conferred by the subculture to those members who excel at fighting, who are physically aggressive, and who display an all-around disregard for middle-class standards. Because of their repudiation of the conventional culture and deep reliance on their own social milieu for status, members of the delinquent subculture develop a strong dependence to their system for identity. This trait helps to uphold its distinct degree of permanence across contexts.

Sociological theorists maintain that in the wider culture actors rely on substantial educational achievement, occupational advancement, and the acquisition of rare or expensive material items to demonstrate marked success along conventional lines. Success measured in this sense is a constant across time in American society. Cohen argued that marked demonstration of aversion to conventional standards becomes a valued end for the lower class in much the same manner as conventional goals for those who are more advantaged: The lower-class value set is made known through what he considers class-based interaction. Relying on the group as the catalyst for behavior-strain-based subcultural models therefore effectively merges the interactive component of earlier models, addressing the atomistic limitation of strain theory. At the same time, the strain-based model pinpoints the etiology of the contemporary delinquent subculture as a collective and violent reaction formation against conventional culture. It also expands on the work of the Chicago School, positing that the reservoir of identity provided by the subculture incurs its transmission.

Other theorists in the strain-based tradition of subcultural theory, however, take issue with the idea that frustrated individuals reject the American success goals and formulate their own status system. Two theorists, Richard Cloward and Lloyd Ohlin, questioned the notion of the ubiquity of a violent reaction among the lower class. In contrast, they developed a variant of the strain model, labeled the *opportunity theory of subcultures*, in which they posited that youth facing strain seek out illegal solutions (e.g., hustling, robbery) in their own social environment that permit them to attain conventional success. What distinguishes this model from Cohen's subcultural theory is the notion that the circumstances of actors' neighborhood determine the availability of illicit income-generating opportunities and ultimately success by illegitimate means. Thus, norms in favor of success through illegal means are locally situated according to the opportunity model. The transmission of values suggesting crime in an appropriate means is, however, contingent on the extent to which it is an entrenched property in one's neighborhood. So, in this sense, culture is transmitted through social interaction—as others suggest, however, the neighborhood more or less makes available the subcultural protocols. A logical implication implies that as the subcultural complex wanes in intensity over time—if in fact it does—so should the behavior it sanctions.

Conceptual models framed around class position, in the manner as those noted earlier, are often referred to by social scientists as *theories of relative deprivation*. An alternative branch of subcultural theory, in contrast, claims that a subcultural value complex is the symbolic aspect of a given class structure and does not originate from, nor is consciously propagated by, class differences. Instead, the subculture is simply part of the class itself, and to the extent to which this is true the subculture arises from a person's absolute position in the class structure. To reiterate, a central component of both theories is the actors' structural position, yet they take widely different positions on this point. More specifically, theories of absolute position assert that lower-class delinquents are not motivated to violate the law by a referent value complex, but their actions are dominated by the dictates of their *absolute* position as members of the lower class, whereas strain-based models assume that delinquency is produced by the awareness of those in the lower class of their lack of access, relative to the affluent, to the means of attaining socially defined ends.

A prominent subcultural model focusing on the importance of absolute structural position was put forth in the late 1950s by Walter Miller. According to Miller, the lower-class cultural system is distinctive in its symbolic content, or what are referred to as *focal concerns*. Focal concerns are analogous to values in the sense that they represent components of a culture and that each attracts deep emotional involvement. Focal concerns (or values) include trouble, toughness, smartness, excitement, fate, and autonomy. A unique feature of social life among the lower class is the "adolescent street corner group." This single-sex social conglomerate provides a certain degree of affective and material resources unmet in the widespread absence of the two-parent family unit. Participants are socialized to the normative demeanor of the male sex role, an opportunity not otherwise available in their surroundings. Two additional focal concerns—"belonging" and "status"—are critically important to the lower-class peer group. Each is a by-product of adherence to the general array of focal concerns held by the lower class. The concept of belonging implies a preoccupation with in-group membership, and the concern with status refers to the desire of youth to achieve a position of good standing among group members. Personal status or rank is earned by exhibiting skills in the behavioral hallmarks of toughness and smartness. Showing physical prowess in the face of a rival group incurs a reputation for toughness, a quality that engenders a high ranking in one's group. For lower-class youth to closely conform to the normative imperatives of their group is to act in a manner inconsistent with the conventional values of wider society. Therefore, in direct contrast to a strain-based subcultural perspective, Miller's model asserts that criminal involvement by lower-class youth is not motivated by the desire to defy the lofty demands of the middle-class value system. Such a logical configuration is advocated by those who use the middle-class principles as a point of reference.

With regard to the permanence of the lower-class subculture, Miller suggested that lower-class culture is transmitted over time to the extent that lower-class persons aspire for membership into street corner groups. Membership, again, is granted to those who overtly commit to focal concerns; however, here the causal role of the cultural and structural components of Miller's subculture model is imprecise. As explicated earlier, reaction formation models more clearly defined the structural genesis of the subcultural system and described how its continuity arises from members' increased reliance on its cultural precepts. However, the group concept in the model of absolute structural position assumes a more autonomous form; in other words, it exists independent of other class-based systems. In the early strain-based depiction, the group establishes an autonomous norm structure, yet it subsists—at least initially—by virtue of its polarization against middle-class standards. Again, the logical juncture at which the two branches of subcultural theory differ is on the origins of the subculture and its transmission. With regard to the latter point, it is unclear whether in the theory of absolute position the actor is predicted to shed the lower-class preoccupation with focal concerns in favor of more conventional values if he or she were to escape the lower class. Furthermore, the question remains as to whether the reaction of the lower class in the Cohen's account would diminish if they were unable to align themselves with like-minded others.

Subcultural Theories and Empirical Validity

Empirical researchers have found some support for theorists' claims with regard to the class origins of subcultural values; nonetheless, the evidence is ambiguous at this point. For instance, studies show that middle- and lower-class non-gang and gang members positively value conventional standards, but this same body of findings shows that with a decline in one's social class level the salience of *proscriptive* norms grows increasingly untenable. Lower-class participants' behavior is also less consistent with their values, suggesting that the degree to which they actually conformed to middle-class standards is weaker than that among their higher status counterparts.

In support of subcultural accounts, qualitative evidence indicates that lower-class boys place greater value on displaying a tough-guy reputation and being skilled at fighting. Other researchers who have used nationally representative data in a quantitative approach have discovered that youth of lower socioeconomic status are more apt to commit violence because they have acquired definitions favorable to violence through interactions with members of their social milieu, especially family. Also, studies have revealed that nonconventional attitudes mediate the pathway between actors' class position and violence. What the latter collection of findings conveys is that, indeed, subcultural systems are

structural in origin and produced by key agents of socialization who comprise one's same class position.

Another branch of subcultural theory, developed by Wolfgang and Ferracuti, departs from those already described in that it gives little explanatory power to structural factors in producing patterns of violence. It is considered a pure subcultural theory because it virtually ignores the role of broader structural factors. Wolfgang and Ferracuti interpreted rates of violent crime among groups and collectivities as evidence that the group—for instance, African Americans—holds attitudes that favor violent conduct. Their theory of subcultures bridges racially differentiated patterns of violence with oppositional value orientations, construing social structural factors with a relatively minimal degree of explanatory power. Wolfgang and Ferracuti stressed that a subculture cannot fully differ from the wider culture. According to this view, societies tend to have a common value pattern to the extent that even subcultures remain within the wider culture. The subculture and wider culture are, in essence, cultures in conflict. Wolfgang and Ferracuti further argued that social groups modulate conduct norms, and for conduct norms or values to be salient they must be situationally invariant; if not, they reflect no enduring allegiance. Moreover, normative systems develop around values in that values engender the normative standards relating to proper behavioral responses. Pure subcultural theory, however, allows for values to affect behavior independent of propinquity to like-minded others, unlike strain-based accounts and even those of the Chicago School.

According to Wolfgang and Ferracuti, the extent to which people identified with subcultural values is made obvious to the observer in light of their actions. Their theory focuses largely on understanding the cultural foundation underlying "passionate," or nonpremeditated, acts of homicide. To the perpetrators who commit this category of crimes they impute the subculture of violence. People occupy a subculture of violence by virtue of the fact that they are violent. Many scholars conclude, however, that this approach is tautological. Theorists insist that among groups who display the highest rates of homicide the subculture of violence should be most intense. An actor's integration into the subculture (measured by behavior) reflects his or her degree of adherence to its prescriptions for behavior. Violence does not represent the constant mode of action among subcultural members. Wolfgang and Ferracuti argued that if this were the case, the social system itself would become debilitated. In this regard, their perspective is relatively limited in scope because it illuminates only the value set that translates situations into violence, instead of the entire array of values held by a class position.

With regard to the etiology of subcultural traditions, the pure subcultural theory advocated by Wolfgang and Ferracuti remains intentionally silent. It implies that structural factors may contribute to the genesis of subcultures through the process hypothesized in strain-based accounts.

However, the model suggests that norms favoring violence are perhaps causally related with socioeconomic factors. For instance, it indicates that the concentration of a sub-cultural orientation among African Americans, as reflected by their involvement in homicide and assaultive crimes, may be a product of the urban deterioration and economic disparities affecting this population. However, they made no consistent and precise statement about the linkage between social structural factors and the subcultural tradition they delineated. It is interesting, however, that the theorists appear to contend that it is structural factors such as poverty and deprivation that account for the generational transmission of the subculture. People who are beleaguered by impoverished conditions become frustrated and aggressive. Parents are hypothesized to pass this experience on to their children, in whom it blossoms fully into a subculture of violence. To prevent the continual cycling of the sub-cultural tradition, pure subcultural theory suggests that the persons who carry it should be forcefully dispersed and resocialized into the middle-class system. For some analysts, this programmatic implication of their theory makes it less palatable on the whole.

Subcultural Theories Today

More recently, scholars of the subcultural tradition have focused on the dynamics of contemporary urban America, including widespread joblessness, high rates of concentrated poverty, and general urban structural decay. An important aspect of a contemporary approach is explicit attention to the experience of urban African American males and their disproportionate involvement in violent crime. Early pure subcultural theories, such as Wolfgang and Ferracuti's, largely circumnavigated the political and social structural dimensions of violence and in the process emphasized the existence of a counterproductive culture among groups who demonstrate extensive involvement in violence—namely, African Americans as well as lower-class persons. Contemporary approaches expand on this tradition and study the symbolic or normative aspects of violent actions among urban blacks. Current models, however, take a step forward by examining the social structural, historical, and political backdrop against which these values subsist.

Violent crime rates climbed in America's cities throughout the 1970s and 1980s. By the early 1990s, rates of homicide involving black youth peaked to an unprecedented level. Sociological studies of the urban economy during the 1980s were crucial to understanding this phenomenon because they systematically unraveled the sheer magnitude of the structural component behind urban violence. This work reveals that urban communities are distinguished by a disproportionate concentration of the most disadvantaged segments of the black population. The coexistence of structural deprivations undermines the formation of dense person-institution networks; as a consequence, the urban poor

are socially isolated from mainstream roles. Urban sociologists propose that alternative behavior protocols emerge in such places. In their view, these *socially structured cultural processes* are less apt to assign negative sanctions to deviant behaviors, and thus the probability of violent actions is magnified.

It was in this intellectual context that ethnographers researched the cultural mechanisms driving violence in contemporary urban America. The contemporary cultural perspective is not unlike urban sociologists' with regard to how structural organization affects the values toward behavioral protocols, and it shares themes found in earlier ethnographies demonstrating the diversity of conduct norms among residents of urban centers. However, current cultural theory differs primarily from urban sociologists' ideas in that the cultural substrate they define purportedly sanctions the use of violence, whereas urban sociologists' conceptualization holds that violent behavior is less condoned or tolerated. More critically, this new branch of cultural theory suggests that for black males (and females) in disadvantaged urban areas, their very identity is constructed early in life according to the standards of the oppositional culture. In fact, Elijah Anderson proposed that the social alienation brought about by economic transformation has spawned an oppositional street culture or street code in inner-city settings. It supplies the rules regarding the proper way to defend oneself, and at the same time it assigns the normative rationale for those seeking to provoke aggressive actions. The code serves as a shared relational script by which both victims and offenders must abide if they are to successfully navigate their precarious social world. The ideas of early and more recent subcultural models are similar in this respect, because advocates of each argue that the nonconventional culture they observed is useful in the ecological context in which it exists.

According to Anderson, the content of the code is composed foremost of the rules to achieve honor. Deference is a valuable commodity in the subculture. Someone who is respected is better equipped to avoid potential threats of violence plus the unwanted situation of being bothered by others. Perhaps more important, however, respect is an end in itself that affords the luxury of self-worth. By displaying a confident demeanor and wearing the appropriate attire, actors communicate a predisposition to violence. The street code requires actors to express their willingness to engage in physical aggression if the situation demands it. When an attack occurs, the code dictates that it should be met with a retaliatory response of like proportion; otherwise, respect is undermined, and the victim invites future attacks. With regard to victimization, how people respond illuminates the broad cultural disparities between the conventional and the oppositional system. In the case of the former, victimized individuals will either contact formal authorities or move on without rectifying the situation despite the degradation they experienced. In contrast, people whose existence is dominated by the imperatives of the

street code actively pursue a strategy for revenge. The former group's status does not hinge on whether its members avenge their aggressor; instead, rank is determined by their merit in conventional avenues.

Contemporary cultural models observe that not everyone accepts the oppositional culture as a legitimate value system; instead, in Anderson's view, the urban landscape is occupied by two coexisting groups of people: (1) those who hold a "decent" orientation and (2) those whose lives conform more closely to standards of the code—a group Anderson refers to as "street". The mechanism by which the street code is transmitted as a cultural system is said to occur not only through public exposure to manifestations of the code but also through socialization into the code that occurs in the street home.

According to Anderson, decent people socialize their children according to mainstream values. They believe that success is earned, in part, by working hard and maintaining a law-abiding lifestyle. Parents in decent families rely on strict methods of discipline to socialize their children according to mainstream values. Cognizant of the hazardous social environment they occupy, decent parents establish curfews and keep a watchful eye on their children's activities.

As opposed to decent families, street families are more devoted to the oppositional orientation embodied in the code, according to Anderson. Their interpretations of their reality as well as their interpersonal behaviors rigidly conform to its standards. Their orientation approximates that held by youth in the subculture envisioned by some strain-based accounts. The cluster of values by which street folks abide are antithetical to the values of middle-class, conventional existence. Street families place less emphasis on work and education, which is underpinned by their deep distrust in the formal structure as a whole. Most are financially impaired; whatever income they earn is misused, spent on other priorities, such as cigarettes and alcohol. Children of street families witness numerous incidents suggesting that violent aggression instead of verbal negotiation is a means to achieve a desired end. For youth reared in street families, their unfavorable early life experiences and the inept, aggressive socialization they receive culminate to shape their strong proclivity toward an orientation consistent with the street code. The cultural standards to which decent and street families adhere are diametric opposites. Because both groups are immersed in the same contextual environment, their orientations are prone to clash, although the aggressive posture of the street orientation generally prevails. Because of this circumstance, decent folks have an incentive to become intimately familiar with the behavioral imperatives of the code; moreover, they must be prepared to momentarily perform them.

With respect to empirical evidence, findings generated from survey data are inconsistent with the postulates of Wolfgang and Ferracuti's subcultural model, suggesting scant evidence of between-group (e.g., race) differences

with regard to support for the dictates of an oppositional subculture. Multilevel research also shows that blacks hold more negative views toward the agents of government authority (e.g., police, courts), but after incorporating neighborhood measures the relationship diminishes, suggesting that blacks' attitudes are strongly influenced by their contextual circumstances. Quantitative studies also examine the purported association between people's adherence to the oppositional subculture and unlawful behavior. The combined result of this work is somewhat ambiguous. Some investigators have explicitly examined the linkage among race, oppositional values, and patterns of violence implied in subcultural theory. Some have found that blacks are more likely to commit violent prison infractions in comparison to their white counterparts, suggesting a contextual invariance of behavior among the black population, which supports early pure subcultural models. Macrolevel research uses census data to investigate the validity of the subculture of violence thesis as it relates to violence across population segments. Using this method, researchers uncover a positive effect of racial composition on violence, net of economic factors.

Other research generates a construct approximating the attitudinal components of the street code. Findings from this work show that youth who reside in disadvantaged neighborhoods and who feel discriminated against are likely to adopt the street code. Results also show that the street code predicts violent delinquency. Similar studies have reported that the street code has a positive effect on individuals' odds of victimization; furthermore, neighborhood disadvantage exacerbates this relationship. Others have found that retaliatory homicides—those reflecting subculture imperatives regarding honor—are more likely to occur in disadvantaged neighborhoods. This finding closely coincides with subcultural theory in general. It also supports more contemporary models that suggest an oppositional culture thrives in places that lack social structural resources, such as poor urban areas, where notions of honor are promulgated as an indispensable ideal.

Empirical evidence thus fails to disconfirm the idea that nonconventional culture plays a powerful role in stimulating violent behavior. However, what appears untenable is the notion that black violence is driven by an inherent subculture. Despite this, research focused on the high rates of violence among the black population has not abandoned cultural explanations entirely. A theory was recently developed that explicates the social ecology of violence, emphasizing both social structural and cultural mechanisms. A point of departure for this model is the inability of early pure subcultural theory to logically account for the uneven distribution of black violence. If pure subculture models are correct in their insistence that blacks adhere to a culture of violence, then rates of black violent crime should be equal across place. This is not the case: Blacks are differentially involved in violence across America's cities. However, this does not render cultural explanations entirely

flawed. Expanding on the Chicago School model, theorists propose that black violence is the outcome of social disorganization as well as cultural social isolation. Both ecological processes arise from structural disadvantage and residential instability. Social disorganization erodes informal regulation, whereas cultural social isolation shapes ecologically structured norms sanctioning forms of conduct. In turn, these mechanisms are hypothesized to jointly impact rates of violence. Such logic assumes that because black communities disproportionately experience structural disadvantage they also disproportionately experience the processes that fuel violent crime. Under the same social structural conditions, blacks and whites should exhibit similar rates of involvement in violent offending. On the basis of these assumptions, nonconventional dictates toward behavior are transmitted as a result of the failure of structural factors to restrain behaviors that represent subcultural preferences. Enabling social organization within a neighborhood would, in theory, diminish the power and the transferability of the nonconventional culture among persons over time.

By the latter part of the 1970s, there was marked level of antipathy toward any notion of a nonconventional culture within criminology. Whether it was a strain-based depiction, one of absolute position or a model of pure subculture, theorists advocating subcultural propositions were targeted by a cohort of scholars who preferred structural accounts. One prominent theorist, Ruth Kornhauser, claimed that the proliferation of oppositional values among groups, in particular those that sanctioned destructive behavior, would cause a society to more or less collapse. On the basis of her reasoning, exchange-based economies are particularly susceptible to violence because it threatens the ability of important resources to flow throughout networks. Kornhauser went on to argue that what other theorists conceived as subcultures are actually collective representations of weakened commitment to conventional culture, a condition produced by social structural patterns, namely, social disorganization. Her interpretation indicates that, were it not for social disorganization, nonconventional protocols would not exist within communities and neither would acts of law violation. Consensus- or control-based studies of crime causation such as Kornhauser's dominated scientific discourse up until the late 1990s. A flurry of published articles centered around the role of social control mechanisms in inhibiting violent behavior. Robert Bursik and Harold Grasmick articulated a systemic model of social organization in the tradition of a social structural position that in essence viewed the persistence of violence as a concomitant product of the persistence of weak social ties and ultimately ineffective public, private, and parochial social controls within communities. Of course, an analogue to their view is that violence is sustained because the cultural conditions underlying it persist. As the tenets of structural accounts became subject to empirical tests, the somewhat limited extent of their explanatory power was revealed.

The trend of antiscultural sentiment within the field has since shown signs of reversal. Indeed, the limits of social structural resources in explaining patterns of crime has forced criminologists to reevaluate the conceptualization of nonconventional culture, its relationship to the reality of structural circumstances in urban America, and the precise nature of the link between normative cultural standards and the commission of violent actions. One fact drives the newfound interest in culture: Certain social settings are persistently beset by extraordinary rates of serious crime, whereas other settings do not experience a high volume of crime even though they lack strong social organization (e.g., suburbs) that is predicted to drive high rates of crime.

A current trend in criminology is to treat culture as an adaptation to the social structure and to consider behavior as endogenous to both factors. Early subcultural models of the Chicago School were in fact criticized for assuming a deterministic order because they implied that the causal chain flows one way, from value systems to action, yet a culture-as-adaptation perspective fails to recognize the independent causal force of cultural symbols. In response to this limitation, researchers have moved away from a subcultural strategy (i.e., values and ends) and have focused on how culture is responded to, mobilized, and re-created through individual choice situated within spatial milieus. The benefit of this perspective is that it recognizes the power of culture to re-create itself through behavioral representation (or modeling) and through cognitive learning. An emerging perspective describes culture metaphorically as a "toolkit" that provides strategies of action enabling actors to navigate their unique social landscape. An assumption of this model is that actions cannot be accomplished without the proper toolkit, and certain actions are more probable if the symbolic means are available. Applied this way, violence is practical to implement as a means if one's toolkit contains the requisite resources, and violent events may be difficult to avoid if repertoires are unavailable that direct one's strategy to do so. Between-person variation in the symbolic resource of the toolkit represents the diversity in socialization experiences between people, part of which is provided by their local ecological setting.

DETERRENCE AND RATIONAL CHOICE THEORIES

RAYMOND PATERNOSTER

University of Maryland

There are many theories about what causes people to begin to commit, continue to commit, and desist from committing crimes (Kubrin, Stucky, & Krohn, 2009). Some of these theories assert that crime is due to a collection of personality traits that incline a person to commit crimes (Wilson & Herrnstein, 1985); some scholars argue that crime occurs when people are led by their culture to want something, such as monetary success, but are denied access to the means to achieve these things (Agnew, 1992); and still others claim that crime occurs when people get socialized into cultures, subcultures, or groups that either actively promote or at least openly tolerate criminal behavior (Nisbett & Cohen, 1996). A deterrence, or *rational choice theory* of crime (let's call it *RCT*), is none of these things, and because deterrence theory can be considered a subtype of *RCT*, this chapter's discussion will mostly focus on the latter.

Deterrence can be thought of as a subtype of *RCT* because they share a great deal of common conceptual ground, with *RCT* being a more general theory than deterrence. Deterrence theory argues that criminal acts are inhibited or deterred because of the punishment that can be associated with crime (Andenaes, 1974; Zimring & Hawkins, 1973). For example, when someone thinks about committing a crime but refrains from doing so because he fears that he might get arrested, that person is said to be deterred by the fear of a sanction or penalty, in this case, an arrest. This is an example of *general deterrence*. General deterrence

occurs when someone who has not yet been punished refrains from committing a crime because of the punishment he or she *may* receive should he or she get caught (Andenaes, 1974). In this case, what deters the would-be offender from committing crime is the fear of a formal or legal punishment. When someone just released from prison contemplates committing another crime but refrains from doing so because she fears going back to prison if she is arrested and convicted, she too is said to be deterred by the fear of a sanction; in this case, the sanction is imprisonment, which is another form of formal or legal punishment. This is an example of what is called *specific deterrence* (Andenaes, 1974). Specific deterrence occurs when a person who has just been punished refrains from committing a crime because he or she fears another dose of punishment. In general deterrence, it is the threat of legal punishment that inhibits criminal offending among people who have not yet been punished, whereas in specific deterrence the inhibiting factor among those who have been punished is the threat of being punished again. Notice that any penalty, such as imprisonment, can act as both a general deterrent when it leads the public to conform because of the threat of prison should they commit a crime and as a specific deterrent when it deters an inmate just released from prison from committing another crime.

Deterrence theory was originally developed in the 18th century by the legal/moral philosophers Jeremy Bentham and Cesare Beccaria, who conceived of it in terms

of the threat of formal legal punishment—the sanctions or penalties that are applied by a state or some legal authority. Within the past 25 years, however, deterrence theory has been expanded to also include nonlegal types of sanction threats, such as the threat of social censure by others should one commit crime (i.e., the fear of embarrassment) or the threat of self-imposed punishment with feelings of guilt and shame (Anderson, Chiricos, & Waldo, 1977; Grasmick & Bursik 1990; Grasmick, Bursik, & Arneklev, 1993). If I refrain from committing crime because I think that others close to me will disapprove and reject me, and that fear keeps me from committing crimes, then I am deterred, but by informal sanction threats, not by formal sanction threats. Modern deterrence theory now considers formal (legal punishments, e.g., arrest, conviction, imprisonment) and informal (social or self-censure) sanction threats as part of the theory.

RCT is much more broad and general than deterrence theory because it includes many other factors besides the risk of formal and informal sanctions. The theories are alike, however, in the assumption that human beings are rational and self-interested beings who are affected by the consequences of their actions. RCT likely finds its modern home in an article written by the Nobel-Prize-winning economist Gary Becker (1968). The position of RCT is that criminal behavior is no different from noncriminal behavior in that it is conduct that persons intentionally choose to undertake (i.e., they are not compelled or forced to do crime), and the reason that they choose to commit crime is that they think it will be more rewarding and less costly for them than noncriminal behavior. Let us break this last statement down carefully. RCT takes the position that offenders are not compelled to commit crime because of some extraordinary motivation: Offenders do not have different personalities than nonoffenders; neither were they socialized into a criminal belief or cultural system whose norms require crime (Cornish & Clarke, 1986; Kubrin et al., 2009). In RCT, criminal offenders are actually no different than noncriminal offenders. Both willingly choose their own behaviors, and both choose those behaviors on the basis of a rational consideration of the costs and benefits of the intended action. The rational choice offender, then, is rational and self-interested and chooses to commit crime on the basis of his assessment that it will be rewarding or profitable or satisfy some need better than a noncriminal behavior. This last sentence contains a great deal of complexity and subtlety, so let us explore it in some detail.

The Theory

As implied by its title, rational *choice* theory presumes that criminal behavior, like legal behavior, is not determined by biological, psychological, or environmental factors acting on the person, compelling him or her to commit crimes (Cornish & Clarke, 1986; Kubrin et al., 2009). RCT argues

that people voluntarily, willfully choose to commit criminal acts such as burglary, car theft, and assault just like they willfully choose to do other things, such as work in a grocery store, go to college, or use recreational drugs. In this theory, then, criminal acts are the product of choice, which means that people make decisions about whether to commit crimes. Viewed as the product of human choice, RCT (and deterrence theory) gives human beings what is called in the criminology field *agency* (McCarthy, 2002). People with agency act as if they have free choice or free will over which courses of action they can take—they act as agents on their own behalf. The other side of agency might be thought of as *determinism*—people behave in a particular way not because they want to or choose to do so but because some cause has acted on them to compel them to behave in a certain manner. An example of a more deterministic theory might be some forms of biological theories of crime, such as the theory that violent behavior is caused by an extra male, or Y, chromosome. In the XYY theory of violent offending, males unfortunate enough to be given an extra Y chromosome at birth are at greater risk of violent behavior than males with a more common XY complement.

RCT believes that crime is due to people making choices to commit crimes (Nagin, 2007). If this is the case, why do some people commit crime only some of the time? In other words, on what basis is the choice made to commit crime (and, by implication, non-crime)? The answer is that, in deciding whether to commit crime, people are guided by their consideration of the costs and benefits of criminal behavior and the costs and benefits of alternative, noncriminal behavior. Put most simply, criminal activity comes with both costs and benefits (which are discussed momentarily), and the theory presumes that when people are thinking about committing a crime, they consider the related costs and benefits (McCarthy, 2002). However, there are costs and benefits of not committing crime, and theory presumes that, before making a decision, people consider the costs and benefits of non-crime as well. Consider the following simple example. If I have a need for money that I need to satisfy, there are (let's assume for simplicity's sake) two ways I can behave to satisfy that need. One way to get the money that I think I need is to sell drugs. This involves a deliberate decision to sell drugs to get the money I need, and before I decide to do that, I consider the costs and benefits of selling drugs. A second way that I can get the money that I think I need is to get a job in a factory, or driving a taxi, or working at a construction site. This second line of behavior will get me what I need—money—but also involves various costs and benefits. According to RCT, before deciding which of the two behaviors to undertake, I consider the costs and benefits of both the criminal and noncriminal activity. Notice here that RCT is broader and more general than deterrence theory because whereas deterrence theory argues that criminal behavior is affected by the costs of crime (formal and informal punishments), RCT argues that the decision of whether to commit crime is

affected by the expected rewards of crime and the costs and benefits of non-crime as well. There are a few unanswered questions here, such as: What are the costs and benefits of crime and non-crime that have to be considered? What ultimately determines my decision?

In thinking about selling drugs to obtain the money that I need, we now understand that I consider the costs and benefits of drug dealing. The costs of drug dealing would include such things as the risk of getting arrested and convicted for selling drugs and the legal penalty that may befall me if I get convicted, such as jail time or a fine. It would include the cost of personal harm to me should I go to jail. I would have to consider how easy it would be to sell drugs again if I went to jail and were released back into the community and how easy it would be to get a legitimate job once I started drug dealing and was arrested. Other costs would be the personal danger I would face in selling drugs, such as getting robbed, beaten up, or shot by disgruntled buyers or another dealer. Still other costs would include the possible shame and embarrassment I would feel if the people close to me found out that I was a drug dealer. Finally, there are other personal costs of drug dealing, such as the financial uncertainties involved (Where do I find a consistent supply of drugs? How much do I charge?), the poor working hours and conditions, and the lack of any formal benefits for drug dealing (i.e., no pension plan, no paid vacations). In addition to these costs, however, I would consider the various benefits of drug selling. These benefits could include the possibility of making a lot of money but working a limited number of hours; the ability to sample my own wares; and being able to secure the things that might accompany successful drug dealing, such as a fancy car, beautiful companions, and a fast lifestyle. There may even be prestige and status in some circles for being known as a drug dealer. In the RCT model of criminal behavior, the would-be offender would weigh these various costs and benefits, and the weights attached to each would vary from person to person (i.e., what is costly or beneficial to one person might not be for another).

In addition to the costs and benefits of drug dealing, before deciding which course of action to take I would also consider the costs and benefits of non-crime. In this example, assume that the alternative course of action is to drive a taxi in order to make money. There are many benefits to consider in taxi driving to secure money. First, if I am paid a wage in addition to a percentage of my fares and tips, it will be a fairly steady source of income. My taxi company may offer benefits such as a retirement plan, medical coverage, and some paid vacation time. Driving a taxi is also honest work. I may get to meet interesting people, and the job does not involve heavy lifting. There are, however, competing possible costs of driving a taxi that I would have to consider. For example, taxi drivers are dependent on taxi riders, so I might not make a lot of money on a slow shift when I have few customers. It is likely that I would have to work some nights and be away from my family, and going back and forth from day shift to night shift will be physically and mentally grueling. Taxi drivers do not usually

make a lot of money, many people fail to tip, and some even run away without paying their fare, leaving the cost to the driver to cover. In addition, a taxi driver is an easy target to rob or even shoot and rob. Finally, although it is honest work, driving a taxi does not carry a lot of prestige in most social circles. In the RCT model of criminal behavior, before deciding what to do, the person would also weigh the costs and benefits of the noncriminal alternative course of action (McCarthy, 2002; Piliavin, Thornton, Gartner, & Matsueda, 1986).

There are costs and benefits to be weighed for criminal conduct and costs and benefits to be weighed for noncriminal conduct. The decision to commit crime or not is based on a rational weighing of both of these types of costs and benefits. RCT does not presume that people are perfectly rational in their decision making; that is, they do take shortcuts in collecting information about the costs and benefits of each course of action, they may be misinformed about the various costs and benefits, and they may not properly weigh each factor—but they possess sufficient rationality to engage in some information collection, and they do consider and weigh the consequences of their actions before deciding what action to take. People may be poor decision makers, in other words, but they are decision makers nonetheless, and if they do not possess perfect rationality, they do at least possess minimal or limited rationality.

It is also important to understand that these costs and benefits that are weighed by decision makers are the costs and benefits *as they are perceived or understood by the person doing the decision making*. In other words, the costs and benefits are subjective rather than objective (Paternoster, Saltzman, Waldo, & Chiricos, 1983). For example, one of the costs associated with dealing drugs is the possibility that one could get arrested by the police. There is a certain objective likelihood or chance that people are arrested for drug dealing in the area where I want to deal drugs. For example, if last year there were 100 drug deals in the area where I want to sell drugs, and if only one of the dealers was arrested at some point during the year, then the objective probability that I would be arrested would be 1 out of 100, or .01. Objectively speaking, this is a very low risk of arrest. However, chances are I would not know how many drug deals were going on last year, or exactly how many dealers were arrested, but maybe the word on the street and my own understanding of police competence puts my own estimate of the risk of arrest at .25. This is my subjective risk of getting arrested, and it is this subjective risk, not the objective one, that guides my conduct. The same issue of objective versus subjective would hold for the benefits as well. Most important to me are the subjective benefits I think I would acquire by driving a taxi, not what the objective benefits might be. The important thing to remember is that the various costs and benefits that are considered by the would-be offender are the subjective ones.

So, a person contemplating crime rationally considers the costs and benefits of both crime and noncriminal courses of action. These are weighed much like fruit is weighed on a

scale in a grocery store. If the benefits of crime (when considered against the costs of crime) outweigh the benefits of non-crime (when considered against the costs of non-crime), then for a potential offender there is more *utility* in committing crime than in not committing crime. Utility is the combined outcome of the costs and benefits of alternative courses of action that will satisfy a need (in this case, the need for money), and it might be helpful to think of utility as the profit involved in crime and non-crime. So, if I see more overall utility in crime than non-crime I will be more likely to commit a criminal act to satisfy my need; if I see more utility in non-crime, then that is what I would most likely select. Because I am presumed to be a rational person, the prediction is that I will select the behavior with the greatest utility for me. Moreover, because the utility is the gain I expect to get on the basis of my own subjective judgment, RCT is often thought as a *subjective expected utility* theory of offending (Clarke & Cornish, 1985). In a nutshell, RCT can be described with the following simple equation:

Offend If: Utility of Crime > Utility of Non-Crime

It may be that the utility of crime is greater because the expected benefits are greater than non-crime or because the expected costs are less than non-crime. Whichever the case, the rational choice model of offending presumes that, on average, the behavior promising the greater utility will be chosen. It might be helpful at this point to discuss a concrete example of what an RCT theory of offending might have to say about particular kinds of criminal conduct. Let's start with marijuana use.

Strain theory might account for marijuana use by saying that a person who was under great stress or strain because something bad happened to him or her (failed a test, broke up with a boyfriend or girlfriend, or moved to a new school) and that this stress provided sufficient motivation for that person to use marijuana (Agnew, 1992). Differential association theory might explain marijuana use by noting that some people associate in groups in which marijuana use is practiced and where the norms of the group view marijuana use tolerantly (Matsueda, 1988). This group provides fertile ground for the learning of the technique of using the drug, the opportunity to learn how to interpret its effects, and to receive social support and reinforcement rather than condemnation for using it. According to RCT, however, in deciding whether to use marijuana on any given occasion the would-be user would consider and weigh the following factors:

Costs of Crime

A person who is considering marijuana use might consider the following questions when evaluating the potential cost of the crime:

- *Certainty of formal sanctions*: What is the chance that I would get caught by the police or someone in authority? Could I minimize this risk in some way?

- *Severity of formal sanctions*: If I did get caught by the police or another authority, would something very bad happen to me? Would I have a police record; would I go to jail?
- *Informal certainty of punishment*: What is the chance that I would get caught not by someone in authority but someone whose opinion of me matters and who would disapprove of me using marijuana, such as a parent, teacher, coach, or employer? Would that person be disappointed in me?
- *Informal severity of punishment*: If that person did catch me, would something very bad happen to me as a result?
- *Guilt or shame*: If I were to get caught by anyone, would I think less highly of myself?
- If I were to use marijuana, would I have to admit drug use on any job applications, or if I wanted to join the armed services? Would marijuana use disqualify me?
- Could I successfully fake my way in school, at home, at work, if I got high?
- How much does the marijuana cost?

Benefits of Crime

- How much pleasure or fun would it be to get high?
- How much would my friends respect me and think I was cool if I got high?
- Would my self-esteem increase if I demonstrated to myself that I could get high and hide it from others?

Costs of Non-Crime

- Would my friends ridicule me if I just walked away and did not get high?
- Would I not have as much fun if I were not high?

Benefits of Non-Crime

- Would I be able to do my homework, perform better at my job, if I were straight and not high?
- Would I feel better about myself if I were able to resist this temptation?
- Could I use the money that I would have spent on the marijuana on a better cause?

If, after weighing all of these considerations, the would-be offender determined that the utility of using marijuana was greater than the utility of not using it, then he or she would be at greater risk of marijuana use.

Empirical Support for Deterrence and Rational Choice Theory

Deterrence and rational choice are simply theories about how we think crime is brought about, and they may or may not provide accurate understandings of crime. One of the important ways that professionals in the field of criminology and

criminal justice determine the worth or value of a theory is by evaluating the extent to which it fits the facts. A good theory is one that enjoys empirical support when a researcher empirically tests in the real world the propositions or hypotheses that can be derived from the theory. For example, if deterrence theory is true, one could make the following hypothesis about homicide rates and subject this hypothesis to empirical testing:

Deterrence hypothesis: Because capital punishment is a more severe punishment than life imprisonment, then states that have the death penalty as a possible punishment for murder should have lower murder rates than states that punish murder with life imprisonment.

This hypothesis is consistent with deterrence theory because it argues that would-be offenders are affected by punishments or costs. Because the death penalty is more costly to the offender than life imprisonment, would-be murderers in states with the death penalty face a more severe punishment than would-be murderers in states that administer only life imprisonment. One way to find out if deterrence theory is correct, then, would be to compare homicide rates in states that have the death penalty with states that have life imprisonment. A large number of empirical studies have been undertaken over the past 60 years with this goal in mind (Paternoster, Brame, & Bacon, 2008). Unfortunately, the evidence with respect to this hypothesis is not very convincing. Although the research has generated a great deal of controversy and the findings have been subject to considerable dispute, it seems that the safest conclusion is that there is no unequivocal evidence to date that the death penalty is a more effective deterrent to murder than life imprisonment. Does this mean that deterrence theory is false? Of course not; there are other ways to test the predictions of the theory.

Other empirical tests designed to examine deterrence theory have shown more convincingly that the fear of formal and informal punishment may indeed act as an effective general and specific deterrent to crime. With respect to formal sanctions, there is evidence that, although its effect is not large, the use of imprisonment serves as an effective deterrent and the national increase in the use of imprisonment in the 1990s may have been responsible for some part of the decline in crime (Levitt, 2001). Police studies have shown that when high-crime areas, known as “hot spots,” are saturated with extra police patrols (in light of the fact that increased police presence in a high-crime area increases the certainty of punishment), crime generally goes down (Sherman, 1990). Other kinds of police crackdowns, such as highly publicized roadside sobriety tests, have shown that the incidence of crime—in this case, drinking and driving—goes down, at least in the short term (Ross, 1984).

Over the years, numerous studies have tested whether not only sanctions that are actually imposed deter crime (e.g., arrest, conviction, imprisonment) but also whether both

formal and informal sanctions that people think or *perceive* will be imposed act as a deterrent to crime (Paternoster, 1987; Pratt, Cullen, Blevins, Daigle, & Madensen, 2006). For example, people can be asked the following question to capture how certain they think they will be caught for a given crime: “On a scale of 1 to 10, where 1 is ‘I’d get caught every time’ and 10 is ‘I’d get away with it every time,’ how often do you think you’d get caught by the police if you used marijuana?” This measures the *perceived certainty of formal punishment*; people with low scores have a high certainty of punishment, and those with higher scores have a lower certainty of punishment. If deterrence theory is true, one would expect the former group to be less likely to use marijuana than the latter group, because they have been deterred. If one added the phrase “caught by your parents/dorm advisor/employer,” one would have a measure of the *perceived certainty of informal punishment* and could predict that people who think they will not get caught by another would be at a higher risk of using marijuana than those who think they will more likely get caught. To measure the *perceived severity of informal punishment*, they could also be asked questions that pertain to “how much of a problem it would be” if someone found out about them committing a crime. Research studies that have used this method and various other similar approaches have generally found that the perceived certainty (but not generally the severity) of formal sanctions has a weak deterrent effect, whereas the perceived certainty and severity of informal punishment have a stronger deterrent effect (Pratt et al., 2006). In sum, although there may be some dispute as to how large an effect formal sanctions may have on crime, there is little dispute in the field that formal punishments either by the police, the courts, corrections, or some other criminal justice agency does seem to lower crime. There is also less disputed evidence indicating that the kinds of informal sanctions imposed by others in our lives act as an effective deterrent to crime. These findings from deterrence theory regarding formal and informal sanction threats provide indirect support to RCT as well, because RCT would make the same prediction that a high cost of crime would tend to reduce crime. Furthermore, this implies that people do respond to the expected consequences of their actions and that they are rational enough to be deterred from committing some crime when they think the penalties are certain and perhaps high.

In recent years, numerous attempts to measure the predictions of the rational choice method have been made. One stream of research is policy oriented and examines what is called *situational crime prevention*. In some of this research, active and “retired” criminals are extensively interviewed about what factors entered their decision to commit crime in general and/or a specific offense (Cornish & Clarke, 1986; Kubrin et al., 2009). Supportive of RCT, offenders frequently cite factors related to the costs and benefits of offending, such as the ease with which they can enter and leave a possible crime site, what the expected

payoff for the crime is, the perceived ability to avoid detection, and their capacity to get what they want legally rather than illegally (Clarke & Cornish, 1985). More quantitative research also generally supports the rational choice model of offending. These studies have asked would-be offenders about the expected costs and benefits of criminal activity, and the results indicate that the decision to commit a crime is based at least in part on the expected costs and rewards of offending (Grasmick & Bursik, 1990).

It should also be noted here that whereas it may be intuitive to think that a rational choice view of offending might apply to property or instrumental crime, it might not also apply to crimes of violence, such as armed robbery, murder, or sexual assault; neither would it be able to explain what might be thought of as compulsive kinds of behavior, such as drug addiction. In point of fact, RCT has been used to adequately explain a variety not only of what might be thought of as instrumental crimes, such as robbery, burglary, and shoplifting but also expressive crimes, such as sexual assault and crimes of compulsion (e.g., drug addiction; Cornish & Clarke, 1986). A rational choice model has also been applied to the study of terrorism, and terrorists have been shown to rationally respond to increases in the costs of their crimes (Dugan, LaFree, & Piquero, 2005). RCT is, then, a very broad and general theory of crime that is able to explain property, violent, drug, sexual, and politically motivated offenses (Weisburd, Waring, & Chayet, 1995).

Applications

Think for a moment about what deterrence theory and RCT say about what causes crime: Crime will occur whenever a would-be offender thinks that the advantages or benefits of crime outweigh both the costs of crime and the benefits and costs of non-crime. This means that there are several different avenues by which to pursue public policy if one wanted to reduce crime through an appeal to RCT. To reduce crime, one or all of the four following general actions could be taken:

1. Increase the cost of crime.
2. Increase the benefits of non-crime.
3. Reduce the benefits of crime.
4. Reduce the costs of non-crime.

Sometimes these policy paths would overlap such that when we increase the cost of crime we may also be increasing the benefits of non-crime. However, with these four general points in mind, we can briefly explore the crime-reduction possibilities of RCT.

Increase the Cost of Crime

One of the most frequently taken paths of criminal justice policy is to enhance the formal penalties for crime

with the expectation that such an increase will lower the commission of that particular crime (and maybe others, if there is a spillover effect whereby if we punish more severely for Crime X it also inhibits people from committing Crime Y). Readers who think about the major criminal justice response to the increase in crime during the 1990s and early 21st century will discover that most states responded by increasing the number of people in prison and increasing the length of time inmates were spending in prison. A reduced use of probation, “get tough on crime” judges, “three strikes and you’re out” policies, increased use of the death penalty, the end of parole, and greater use of mandatory minimum sentencing guidelines are but a few of the criminal justice “reforms” that have taken place over the past 20 to 25 years. If you ask yourself, “What was the expectation that policymakers had when they created these programs?” you will quickly conclude that the policymakers thought that by increasing the certainty of punishment (the number of people who go to prison) and the severity of punishment (how long people stay there), crime will be reduced. They thought this because they assumed (either implicitly or explicitly) that offenders and would-be offenders are rational beings who take into account the costs and benefits of their behavior, and if a behavior is made more costly with enhanced punishment, then rational people will be disinclined to commit it.

Whether they realize it or not, proponents of a “get tough on crime” stance usually are assuming a rational choice view of crime. In fact, rational choice assumptions permeate the criminal justice system and form its foundation. Former President Bill Clinton made as one of the important supports of his crime control policies the requirement to hire 100,000 new police officers and put them out on the streets. He might not have explicitly said that his policy was based on RCT, but it was. Increased numbers of police officers increase the expected cost of crime by increasing would-be offenders’ perceived certainty of getting caught and arrested (on the assumption that the more police officers there are on the streets, the more eyes there are watching you). Thus, under the assumption that offenders and would-be offenders contemplate the risk of incurring a cost, the idea of putting 100,000 new police officers out on the streets was based on RCT and deterrence theory.

Frequently, then, when there are calls for more police, less plea bargaining in courts, more prison terms and less use of probation, and more certain and longer prison terms, these calls are based on the expectations of RCT that such measures will increase either the objective or expected costs of crime and, other things being equal, will reduce the level of crime.

Increase the Benefits of Non-Crime

Increasing the costs of crime is only one way under deterrence theory and RCT to reduce the level of crime;

one can also lower crime by increasing the benefits of activities that compete with crime. For example, one of the reasons kids in inner-city neighborhoods get involved with crime and drugs is that they get thrills or some kind of “kick” out of doing it. In other words, crime and drug use supplies them with a rush. One way to inhibit crime would be to get kids involved in other activities that are legal (non-crime) that can provide them with some sort of pleasure/fun/relief from boredom. In the 1990s, there was an effort to get inner-city kids involved in midnight basketball programs, because it makes perfect sense to provide a pleasurable noncriminal activity as an alternative to crime if you believe in the assumptions of RCT. Recall that the theory holds that people consider the costs and benefits of both crime and non-crime before making a rationally based decision as to what to do. This means that when these programs are set up, inner-city youth will weigh the costs and benefits of crime along with those of midnight basketball. Before they choose crime or drug use, then, youth will be in the position of considering the benefits of playing basketball, and this might (together with the lesser cost of a basketball injury vs. an arrest for crime or drug use) be substantial enough to tip the utility balance toward non-crime rather than crime.

A similar example can be used for adults and adult crime. One of the ways to increase the benefits of non-crime would be to provide vocational opportunities and jobs to individuals who are at high risk of committing crimes as well as to make it easier for those who have already committed crimes to turn away from it in favor of more conventional opportunities. The Job Corps, for example, is an educational and vocational training program run by the U.S. Department of Labor for youth 16 through 24 years of age. It targets youth who by most accounts would be considered at high risk for committing crimes—young, mainly minority males, from urban areas—and helps them finish high school, earn a GED, learn a trade, and find a job and keep it. The whole purpose of the Job Corps is to take young people with a bleak future and train and educate them so that they can find well-paying jobs and become productive citizens. The Job Corps program, then, provides a direct alternative to criminal opportunities so that to the extent to which the training and long-term vocational prospects surpass those provided by illegitimate opportunities, the route of job training and education will be selected over crime.

Reduce the Benefits of Crime

There are a number of ways that the benefits of crime can be reduced. Among the characteristics of crime is that it is generally the easiest way to satisfy one’s needs—so, for example, if I want to have a car, one of the easiest ways to get one would be to steal one or buy a stolen one at a great discount. The benefits of crime can be reduced if

crime is made more difficult in addition to more costly. The benefits of auto theft, for example, would be dramatically reduced if people would not leave their keys in the ignition, if they would lock the car, or if they would purchase an inexpensive car alarm or car location device. These things make stealing a car more difficult and therefore less beneficial. The benefits of burglary can be reduced by making it more difficult for a thief to break into one’s home or apartment. Trimming the bushes around the windows so they can be seen from the street is a good idea; having outside motion-sensitive lights is another. Home burglary alarm systems are another way to make burglary more difficult. We can make it more difficult for thieves to fence stolen goods by etching our names or other type of identification on portable objects in our homes, such as computers, televisions, or stereo systems, which are highly attractive targets for thieves. Heroin use provides an analogy: One of the benefits of heroin use is that it reduces the strong physiological craving for the drug. If there are alternative, legal drugs, such as methadone or LAAM (levo-alpha acetyl methadol), that can, under proper medical supervision, similarly reduce the craving, then the benefits of heroin use and its attraction will be reduced. In sum, any action on the part of society as a whole or individual potential victims to make crime more difficult, more time consuming, less financially lucrative, are ways to reduce the benefits of crime. Under RCT, if the benefits of crime are reduced, then crime will be less likely because it has less utility or is less profitable. Although these kinds of crime prevention practices have been most frequently associated with another criminological theory, *routine activities theory*, the ideas of routine activities are perfectly compatible with a rational choice view of crime.

Reduce the Costs of Non-Crime

A final way to reduce crime according to RCT is to lower the cost of engaging in conventional behavior. The following is just one example of how the costs of being conventional can be reduced. A consistent finding from criminological research is that about two thirds of inmates released from state prisons return to crime after being released. One of the reasons why so many ex-offenders commit crimes upon release is that we make it difficult or costly for them to become “normal” citizens, to such a degree that crime is easier and has more utility (Petersilia, 2003). If we remove these barriers to or costs of non-crime, chances are they would be more attractive than criminal alternatives. For example, there are barriers that prevent ex-offenders from securing conventional employment that makes traditional, legal work more difficult and costly and crime easier and more attractive. Job applications generally ask the job seeker if he or she has *ever* been convicted of *any* crime; those who respond “yes” are less likely to get the job in the first place and less likely to get promoted if they do get a job. In some states, ex-offenders are legally prevented

from holding a number of jobs, such as in the areas of education, child care, security, and nursing and home health care. The licensing requirements for jobs such as cutting hair or collecting garbage often preclude those who have been arrested or convicted of a crime. Public employment (working for local, state, or federal government) is difficult for ex-convicts to obtain and is outright denied to them in six states. Some unions bar ex-offenders. Even if there are no legal barriers, employers are reluctant to hire individuals with a criminal record because they fear the possible legal liabilities. In addition, there are other barriers to becoming a normal law-abiding citizen that ex-offenders must confront that may make non-crime more difficult and costly and if removed would make non-crime less costly and therefore a more attractive alternative to crime. Felons are barred from voting, and in some states even the conviction for a single felony bars the person from voting for the rest of his or her life. Public housing and welfare benefits are frequently denied people who have been convicted of a felony. For these and other reasons, therefore, it would appear that we have made a life of non-crime so difficult and costly for ex-convicts that even if they wanted to change, the costs are much higher than continuing in crime.

Conclusion

RCT presumes that there is no strong or compelling motivation to commit criminal acts; instead, crime occurs when someone rationally thinks that a criminal course of action has more benefits and lower costs than a noncriminal alternative course of action. RCT theorists believe, therefore, that offenders are rational enough to calculate the costs and benefits of both criminal behavior and conventional behavior and that they will generally choose the behavior with the highest utility. This does not mean that people collect all necessary information before they make a decision, or that they perfectly weigh the various costs and benefits of offending and not offending. RCT simply assumes that people are rational enough that they are affected by what they think to be the gains and losses of various courses of action. RCT has been used to understand a wide variety of criminal offenses (property, drug, violent, sexual, and white-collar offenses) and is one of the most general theories in criminology. A belief that offenders rationally choose to commit crimes is also a foundation of the criminal justice system and can be easily used as a basis for many crime prevention programs.

FEMINIST CRIMINOLOGY

SUSAN F. SHARP

University of Oklahoma

Criminology has traditionally been one of the most androcentric (male-centered) fields of study in the social sciences. The majority of the research and theory have been based on the study of male criminality and criminal justice system responses to male offenders. Women, when considered at all, have been represented in negative and stereotypical ways, with a focus on their failure to adhere to “traditional” models of appropriate female behavior, as in W. I. Thomas’s (1923) paternalistic view of women. Furthermore, in its quest to be recognized as a scholarly field, criminology has focused on objective empirical research, using official records and large national surveys. The result has been a failure to consider important differences in male and female pathways into crime, types of crime, victimization, and punishments. Feminist criminology seeks to address this limitation by enhancing our understanding of both male and female offending as well as criminal justice system responses to their crimes.

Feminist criminologists seek to place gender at the center of the discourse, bringing women’s ways of understanding the world into the scholarship on crime, criminality, and responses to crime. In the following sections, the focus will be on the emergence of feminist criminology; the range of perspectives and methods used in feminist criminological research; and the maturing of feminist criminology, both in scholarship and in visibility.

The Scope of Feminist Criminology

It is readily apparent that males do indeed commit far more offenses, especially those deemed important to criminology, than females do (see Daly & Chesney-Lind, 1988). This focus has been in part due to the relationship of criminology with legislative and corrections systems. The field developed in part to help improve understanding of why people commit crimes so that policies could be enacted to reduce those crimes. Not only do women commit fewer crimes, but also they commit crimes that are of less interest to those concerned about public safety. Thus, women were largely ignored until the 1970s.

Additionally, the Weberian value-free approach to the study of criminology has failed to recognize that the experiences of the researchers themselves shape and formulate their own approaches to their research. This has resulted in an unreflective supposition that data and theories about boys and men would be generalizable to girls and women. Researchers and theorists have assumed that the study of male crime was the generic study of crime and that women who engaged in crime were more of an aberration than a subject to be studied in and of itself. Ultimately, the feminist approach to criminology emerged from the critique of this practice.

It has been only in the last 30 years that feminist criminology has developed into a recognized perspective in

criminology. However, the term *feminist criminology* is somewhat misleading; it might perhaps be better to speak of *feminist criminologies*. Feminist criminology encompasses a wide range of theoretical perspectives and methodologies that place the ways in which gender shapes experience at the center of scholarly inquiry. It focuses on a broad range of issues related to women and crime, including theoretical explanations of crime, responses to female offending, programming in women's prisons, women as workers in the field of corrections, and the special needs of women prisoners. Feminist thought is not a homogeneous approach; it incorporates the liberal feminist focus on equal opportunities for women, the Marxist feminist focus on class relations and capitalism as the source of women's oppression, socialist feminists' blending of male domination with political and economic structures in society as the source of inequality, and the radical feminist focus on patriarchal domination of women, to name the most well-known branches. However, these feminist approaches have in common their focus on the ways in which the gendered structure of society is related to crime.

Emergence of Feminist Criminology

Until the latter half of the 20th century, most criminological work focused on male offenders and criminal justice system responses to male crime. The lack of attention to female offending stemmed from the fact that most crime was committed by males. However, by the last two decades of the 20th century, female incarceration rates were skyrocketing, leading to a surge in research on girls, women, crime, and the criminal justice system. Many scholars point to the "war on drugs" and the federal sentencing reforms of the 1980s as the primary explanations of the large increase in female prisoners as well as of the emergence of feminist criminological scholarship. Clearly, the war on drugs and federal reforms are the driving forces behind the tremendous increase in the incarceration of women. However, the roots of feminist criminology predate these changes. They are instead found in second-wave feminism as well as in the radical criminology of the 1960s and the 1970s.

The Gender Equality Argument

In the 1960s, scholars began to argue that women were ignored in criminological theorizing and research. This early interest came not from within the United States but instead from Canada and Great Britain (cf. Bertrand, 1969, and Heidensohn, 1968). According to these scholars, the role of gender had been largely ignored, other than noting that males committed more crime. Thus, theories had been developed that could explain the gender gap in crime but that were sorely lacking in being able to equally well explain female crime. The second-wave feminism of the mid-20th century led to a renewed interest in female offenders. Two important books were published in the early 1970s, derived from second-wave liberal feminism's focus on gender equality: (1) Adler's (1975)

Sisters in Crime and (2) Simon's (1975) *Women and Crime*. Although they focused on different aspects of the issue and reached somewhat different conclusions, both argued that the mid-20th-century women's movement changed both female participation in crime and *perceptions of* female participation in crime. Indeed, the central thesis of these two works was that women would engage in more crime as a result of women's liberation. Also, with the focus on equal treatment, the criminal justice response to female offending would become harsher and less "chivalrous."

Both books were important in bringing more attention to female crime and the criminal justice system's response to female crime, but the focus on increased criminal opportunities for women coming out of the push for equality has been critiqued by feminist criminologists. Among the criticisms, two broad themes emerged. First, scholars questioned whether lower-class female offenders were acting out of a desire to achieve equality with male offenders or whether increases in female crime might be due to the "feminization of poverty," because the composition of families in poverty became increasingly dominated by female-headed households. In addition, these scholars pointed out that lower-income female offenders tended to have more traditional and stereotypical views of women's roles, calling into question the idea that these offenders were trying to compete with men in the realm of crime (Daly & Chesney-Lind, 1988). Second, careful analysis of data failed to support the contention that the gap between male and female offending was narrowing (Steffensmeier & Allan, 1996). The focus of feminist criminological thought began shifting to the ways in which social and economic structures shaped women's lives as well as their participation in crime.

The Influence of Critical Criminology

The second major factor in the rise of feminist criminology during the 1970s was the emergence of the "new criminologies," or the radical, conflict approaches to the study of crime. With intellectual roots grounded in conflict and Marxist theory, these perspectives viewed crime as the result of oppression, especially gender, race, and class oppression. Both radical criminology and feminist criminology emerged during the highly political, socially conscious 1960s and 1970s. In the United States and much of the Western world, this was an era of rapid social change and political unrest. Existing ideologies and power structures were challenged, and social movements emerged, including the anti-war movement, the civil rights movement, and the women's liberation movement.

However, feminist criminologists quickly became somewhat disenchanted with what was perceived as the overly idealistic and still male-centered approach of critical/radical criminology. The "new criminology" view of the offender as a noble warrior engaged in a struggle with a powerful state (Young, 1979) also angered radical feminists working to end intimate violence and rape. Feminist criminology began instead focusing on the ways in which a patriarchal society enabled the abuse of women. Radical feminism, with its

focus on the consequences of patriarchy, contributed to the burgeoning body of feminist criminological scholarship.

Radical Feminism and Feminist Criminology

During the early 1970s, radical feminist scholars and activists labored to reform the public response to crimes such as rape and intimate violence. Prior to the revision of policies and laws, rape victims were often blamed for their victimization. Two seminal works during the mid-1970s brought the victimization of women by men into the forefront of feminist criminology and were extremely influential in the development of feminist criminological thought. Susan Brownmiller's (1975) *Against Our Will* was a searing analysis of the role of male dominance in the crime of rape. Similarly, Carol Smart (1976) critiqued mainstream criminological theories, not only for their failure to look at crime through a gendered lens but also for their assumption that victimization was a similar experience for all victims. Smart argued that mainstream theories failed to recognize how the patriarchal structure of society contributed to and shaped the victimization of women.

The contribution of radical feminism to the development of feminist criminology is important for two reasons. First, in collaboration with community activists, radical feminist scholars were able to effect social change. Violence against women became a matter of public concern. Shelters for battered women began emerging throughout the country, and rape laws were reformulated to protect the victims from undue scrutiny. Until the mid-1970s, victims of rape were essentially placed on trial themselves. Proof of rape required evidence that the victim had resisted as well as corroborating evidence. Also, the victim's past sexual conduct could be introduced as evidence by the defense. The feminist approach to rape incorporated the perspective of the victim, and ultimately rape shield laws were enacted that barred introduction of the victim's past sexual behavior into evidence.

Second, the feminist scholarship on rape and intimate violence impacted mainstream criminology. This has led to a revised understanding of the complexities of victimization. Statistics support the feminist position that women's victimization is intrinsically and fundamentally different than that of men. For example, women are far more likely to be victimized by someone close to them. From the radical feminist perspective, this is because social institutions and norms facilitate the victimization of women.

Much like the feminist scholarship on sexual violence, feminist criminological research has helped reshape our understanding of violence within the home and between partners. Much of the early research on intimate violence stems from work using the Conflict Tactics Scale developed by Straus and Gelles (1986). Feminist scholars have pointed out that although this scale measures the *incidence* of a wide range of aggressive tactics, it fails to place them in *context*. Stanko's (1990) examination of *everyday violence* provided evidence that women's victimization was frequently unreported. Thus, research conducted by feminist criminologists,

in conjunction with activism, impacted not only laws but also police practices. Eventually, the National Crime Victimization Survey was reformulated to address the experiences of female victims. Questions about rape and sexual assault were added, as were questions about violent victimization in the home (Britton, 2000). By 1994, the Federal Violence Against Women Act was passed. Prevention and intervention programs were developed, aggressive prosecution was pursued, and funding for research became available. More recently, the International Violence Against Women Act has carried this focus on the rights of women to safety into the international arena.

In summary, feminist criminological thought gained prominence during the highly political era of the 1960s and 1970s. At first, the field focused on the missing information on girls and women in criminological scholarship. As the field grew, the focus shifted to include violence against women as well as the development of feminist criminological theories and feminist ways of approaching existing theories. A broad base of scholarship has been amassed from the women's liberation movement, critical theories, and radical feminism. The following section focuses on feminist approaches to theoretical explanations of crime and criminality. This is followed by a summary of the subject matter of feminist scholarship.

Criminological Theories From a Feminist Perspective

As suggested earlier in this chapter, feminist criminological theorizing is not limited to one approach. Feminist criminologists have adopted many different perspectives, the most noteworthy of which are a feminist approach to mainstream criminological theory, feminist pathways theory, socialist feminist theory, and the most recent development: multiple marginalities/intersectionality theories.

Mainstream Theories and Feminist Criminology

A major thrust of feminist criminology has been the critique of the development of mainstream theories based on research with boys and men. The "add women and stir" approach of mainstream criminology has meant that gender, if considered at all, has frequently been used only as a control variable. Although this has provided confirmation that males are indeed more criminal than females, virtually no information about female criminality can be garnered through this type of research. There are two unspoken assumptions inherent in this approach with which feminist criminologists take issue. First is the tacit assumption that, because males are far more likely than females to engage in criminal behavior, females are somehow unimportant to the field. Second, mainstream criminology assumes that males and females are alike and that what works to explain male criminality will work equally well to explain female criminality.

In particular, theories like Merton's (1938) *strain theory* have been criticized by feminist criminologists for their focus on economic goals and their failure to consider how personal relationships may contribute to criminality. Merton argued that crime was largely the result of having the American dream as a goal but lacking opportunities to achieve this goal in a legitimate manner. Feminist criminologists argued that Merton's theory was obviously not equally applicable to women. They pointed out that, although women were certainly more financially blocked than men, they committed far less crime (Belknap & Holsinger, 2006). Likewise, social learning and differential association theories, with their focus on peer attitudes and behaviors, have been criticized for the failure to take into account the gendered nature of peer relationships. Whereas male delinquency is strongly linked to having peers with delinquent behaviors and attitudes, this is far less true for females. Actually, females who are intimately involved with older delinquent males may be introduced to crime and delinquency by these intimate partners rather than by their peers. Although this is certainly not an exhaustive list of mainstream theories critiqued by feminist criminologists, it does give an idea of the male-dominated approach taken by purportedly gender-neutral theories.

However, other feminist criminologists have argued that mainstream theories may still be used if they are restructured and operationalized in a manner that is more sensitive to the predictors of crime in both men and women. In particular, Agnew's (1992) *general strain theory* attempts to be gender sensitive. By incorporating a broader range of sources of strain in the theory, he has attempted to address the concerns voiced by feminists. In his theory, he has explicitly focused on relationship strains as well as on negative life experiences, both of which are important predictors of female delinquency. Also, he has pointed out that men and women tend to have different emotional reactions to strain, possess different coping skills and resources, and commit different types of offenses (Broidy & Agnew, 1997). A feminist operationalization of general strain theory could explicitly examine the role of abuse histories in predicting female crime. Agnew has argued that it is not strain per se but rather negative emotional responses to strain that lead to crime. Again, a thoughtful and gendered analysis would focus on how emotional responses and coping resources are gendered and how this would help explicate the different relationships between life experiences of males and females and their subsequent participation in crime. Indeed, general strain theory lends itself more to a gendered analysis than most, if not all, of the mainstream criminological theories.

Likewise, life course theories may offer an opportunity for a gendered exploration of women's criminality. These theories not only look at factors important in the initiation of criminal behavior but also examine occurrences that may change the pathways from criminal to noncriminal, or vice versa. In a broad sense, life course theories suggest that it is the salience of an event or reason that determines the likelihood that someone engaging in criminal behavior will cease. In the case of men, this may be marriage or career. However, for women, it may be important to examine other

reasons. In particular, the birth of a child may provide sufficient motivation for a woman engaging in criminal behaviors to change her trajectory to a noncriminal one.

Overall, the gendered use of mainstream theories is not particularly well received by feminist criminologists. Many argue that these theories fail to explore in detail the ways in which the experiences of girls and women shape their lives. In contrast, feminist pathways theory focuses explicitly on the relationship between life experiences and future criminality, arguing that one must consider the role of patriarchal society if one truly wishes to understand female crime and criminality.

Feminist Pathways Theory

Perhaps the greatest breakthrough in feminist criminological theory and research has come by means of the feminist pathways model. In the effort to demonstrate how female crime is inextricably linked to the life experiences of women and girls, this theory focuses on the ways in which women's place in society leads them into criminal lifestyles. In numerous articles and books, Meda Chesney-Lind (see Chesney-Lind & Pasko, 2004) has laid out how childhood abuse and a patriarchal juvenile justice system shape the opportunities of girls, ultimately forcing them into criminal lifestyles. She argues that, unlike boys, girls' initial encounters with the juvenile justice system are largely the result of status offenses, such as running away or engaging in sexual activity. The patriarchal double standard means that girls engaging in these behaviors are seen as immoral and in need of "correction." Girls and women have historically faced institutionalization for engaging in behaviors that were at the most mildly frowned on in males. Indeed, girls suspected of sexual "misconduct" have often been treated more harshly than either boys or girls engaging in criminal activity. It is this patriarchal, paternalistic approach to the social control of the behavior of females that pushes them into contact with the juvenile justice system. Furthermore, there has been a failure to recognize that early sexual behaviors, as well as running away from home, are frequently the result of abuse within the home. Instead of intervening in the lives of abused girls, society has reacted with a double standard that labels these girls as incorrigible and/or immoral. By punishing these girls for behaviors that may actually be self-preserving (e.g., running away from abusive or neglectful homes), society may be further limiting their life chances by identifying them as delinquents. This perspective also examines the relationship between abuse and substance abuse, the number one offense leading to women's imprisonment. Substance abuse is seen as a coping mechanism. Girls and women often use alcohol and drugs to self-medicate their trauma that has resulted from abuse they have experienced. This is an important point, because the majority of incarcerated girls and women have substance abuse problems. Likewise, the majority of these "offenders" have histories of physical, sexual, or emotional abuse. Feminist pathways theory seeks to illuminate the connections between the abuse and exploitation of young females and their subsequent

offending. It is arguably the dominant approach in contemporary feminist criminology.

Socialist Feminist Criminology

It would be remiss in any treatise on feminist criminology to exclude a discussion of how feminist criminology has led to examination of masculinity and crime. As discussed earlier, part of the feminist critique of criminology is the *ungendered* examination of crime. Feminist criminological scholarship has led to efforts to incorporate a clearer understanding of the experiences of both males and females. Messerschmidt (1986) focused on the ways in which patriarchal capitalism structures the experiences of both males and females. He laid out a theory that seeks to explain both male and female crimes of various types and argued that one cannot ignore either economic structures or gender relationships in any true explanation of crime. His theory suggests that marginalized lower class and minority males engage in street crimes because of their blocked opportunities and their roles as males in a patriarchal capitalistic society. In contrast, the structure of gender relations in society tends to relegate women's crime to low-level larceny and fraud.

In keeping with the feminist focus on crimes against women, Messerschmidt (1986) also explored the sexual exploitation of women in the sex trade in third world countries, showing how both patriarchy and capitalism place these women in desperate situations where they submit to exploitation in order to survive. In addition, he drew links between economic inequality and male-dominated family patterns in his discussion of male violence against women. Finally, he provided a masterful blending of theories about male privilege as well as theories about capitalism in his examination of higher level white-collar and corporate crimes, which are committed primarily by males. His work is extremely important to the development of feminist criminology because he directly addresses the feminist criticism that most criminology ignores how gender relations structure crime. His theory illustrates that the feminist approach is cognizant of both men's and women's experiences, seeking to illuminate how gender is intrinsically related to crime.

Feminist Criminology and Multiple Marginalities

As in many of the social sciences, early feminist criminological scholarship has been criticized for its assumption that the experiences of all women are similar. This has led to scholarship that acknowledges the intertwined effects of gender, race, class, and sexual identity. In many ways, the critical race critique of feminist criminology has been similar to the feminist critique of mainstream criminology. The charge is that feminist criminologists have in many ways essentialized the experiences of women, assuming that all women are alike. Proponents of intersectionality and multiple marginality argue that race, class, and gender are each impacted by the social structure and in turn impact individuals. Furthermore,

these impacts interact. It is not simply being female, being African American, being lesbian, or being poor that matters; neither are the effects cumulative. Instead, there is an interaction that evolves from the intersection of statuses. One's actions and opportunities are structured by one's placement along each of these dimensions. Thus, the experiences of, for example, Hispanic women are different from those of Hispanic men as well as white or African American women (Burgess-Proctor, 2006).

Methodology in Feminist Criminology

Not only does feminist criminology encompass many topics, but it also uses many methodologies. Like their mainstream counterparts, feminist criminologists use both quantitative and qualitative methods, often triangulating or combining them to draw on the strengths of each. On the quantitative side, they may examine official data and use large-scale surveys to explore both the relationships between women's experiences and their offending and official responses to women and how those may be colored by gender. In qualitative research, feminist scholars use a broad range of methodologies. In particular, focus groups, in-depth interviews, and life histories provide information to help tease out the complexity of relationships between victimization and offending. Often, a combination is used, with information from surveys or official data suggesting questions to be explored qualitatively and qualitative research informing the statistics (cf. Owen, 1998).

One final aspect of feminist scholarship and research should be addressed. We have seen that mainstream criminology places emphasis on the researcher taking a value-free stance, detaching himself or herself from the subject matter of the research. From the feminist perspective, however, this is an impossibility. The argument is that we are never free of our own beliefs and values, that those shape our research. In addition, the feminist criminological approach suggests the need for *praxis* or *participatory action research*. In contrast to the value-neutral approach of much social science research, participatory action research and praxis-driven methodologies stress the importance of research that is geared toward social change. In feminist criminology, this has meant working toward changes in laws, policies, and prisons. In feminist criminology, as in most areas of feminism, activism and scholarship are intrinsically intertwined.

Feminist Criminological Scholarship

The subject matter of feminist criminology, as in the discipline of criminology overall, includes a broad range of topics. As described earlier, feminist approaches to criminological theorizing have been an important focus. Also, it is evident that violence against women is part of the puzzle. Feminist criminology recognizes that there is not a clear-cut dichotomy of victims and offenders; instead, female offenders are quite likely to also be victims, whether of childhood abuse or abuse as adults (Belknap, 1996).

Furthermore, the motherhood role must be taken into account, and numerous feminist criminologists have explored the effects of large-scale female incarceration on both the women and their children (Sharp, 2003).

Extensive research has examined the offending of women and girls. The bulk of feminist criminological scholarship since the mid-1980s has focused on the criminal justice system's response to female offending. The war on drugs and the federal sentencing guidelines of the 1980s resulted in massive increases in the number of women sent to state and federal prisons. Changes designed to reduce the inequities of indeterminate sentencing resulted in mandatory sentences for lower level female offenders. In particular, aggressive prosecution of drug offenses has impacted women, especially women of color. By the end of 2007, more than 100,000 women were incarcerated for felony convictions on any given day.

This has led to extensive research on the arrest, prosecution, conviction, and incarceration of female offenders. Feminist criminologists also have focused on the conditions in women's prisons and the programs available to female inmates (cf. Sharp, 2003). Two major characteristics of feminist criminological scholarship are evident in the research. First, feminist scholars have consistently argued that the treatment of girls and women in society helps shape their criminal behavior. However, this focus does not end with pointing out the female pathways into crime but instead leads to the second characteristic: Feminist scholars point out that because women and men have essentially different life experiences as well as motivations for crime and types of crime, the criminal justice system should not be designed to treat women the same as men. Thus, considerable recent scholarship has focused on both the problems of incarcerated women and difficulties with how the system is serving them. Some have gone as far as to challenge the gender equity of the corrections systems, arguing that applying the punitive approach designed for men is a form of "vengeful equity," a sort of backlash against women demanding equality. (For a detailed discussion of this argument, see Chesney-Lind 1999, cited in Sharp, 2003.)

This emphasis by feminist criminologists may be better understood by looking at an example. Perhaps a young girl is being physically or sexually abused in the home. Eventually, she may run away, may start using drugs, and may engage in sexual behaviors, perhaps for money or drugs in order to survive. She is eventually caught and remanded back to the custody of her parents. As a result of her behavior, conditions in the home may become worse, with more abuse or unreasonable rules. She again runs away, perhaps getting arrested for drug possession this time. Depending on the location, her status, and perceived resources of her family, she may be placed into a juvenile facility and deemed incorrigible. While there, she experience more abuse. Upon release, returning to her community she finds that she is now labeled as a "bad" girl. She may be behind academically in school; she may have difficulty finding peers with whom she can spend time; and she begins hanging out with an older, tougher crowd. She

meets a young male, several years older, who seems to have ready access to drugs. They eventually become intimate, and she becomes pregnant. By this time, she may be old enough that her parents no longer report her as a runaway. She drops out of school and has the child. The boyfriend leaves, whether through boredom or choice. Now she is a poorly educated single mother, with low self-worth, probably with a drug problem. She has difficulty finding and holding a job. She may steal to support herself, her child, and her drug use. Eventually, she may find another male to help support her. This relationship is likely to be abusive. Her self-esteem becomes even lower, her drug use progresses, and eventually she is charged with felonies and sent to prison. She may or may not have sought drug treatment prior to incarceration. With a dependent child, her options have been limited. She may have been on probation, but her inability to stay off drugs as well as her inability to hold a job and to pay fees makes her a noncompliant probationer. Once she arrives in prison, she finds that there are few programs there to help her with her greatest needs: drug abuse, victimization issues, low self-esteem, education, job training, and planning how to successfully reintegrate into society on her release. Thus, once she is released, she quickly falls into the same behaviors that sent her to prison. She is rearrested, her parole is revoked, and she finds herself in prison again. Her situation is further complicated by the fact that she is a single mother. Her child may be with her family, or social services may have intervened and placed the child in foster care. When men go to prison, the children's mother usually remains with the children, but when women are incarcerated, the majority of the time there is no father present to care for the children, creating hardship for the child as well as the mother. Because women's prisons are often in remote areas, she is rarely if ever able to see her child. If the child is with family members, he or she may be abused, just as the prisoner was as a child. If the child is in state custody, her parental rights may be terminated. Now the woman is more depressed and feels like she has failed at motherhood. The cycle then continues. Without effective interventions that can help her deal with past traumas and resulting mental health issues, the likelihood that she will remain off drugs is low. Without assistance in improving her educational and job skills, building a healthy support network, and finding a safe place to live on release, there is small chance she will be successful when released again.

This scenario illustrates the complexity and interwoven nature of feminist criminology. Theories that illuminate the victimization and experiences of women may help explain their criminal behavior where mainstream theories cannot. Also, the plights of the hypothetical woman just described, and thousands like her, have driven feminist criminologists into the criminal justice system to examine its structure. Awareness of women's pathways into crime points to the need for prisons and prison programs that are geared to the needs of female offenders. Thus, the prison system and programming in women's prisons have become major foci of feminist criminological research as well. Because the

correctional system arose in response to male offending, the needs and abilities of women are often not taken into account. Feminist criminologists demonstrate, through their research on the characteristics of female prisoners, what types of programs would be most beneficial for women as well as which ones might not be effective.

Even substance abuse treatment, vocational rehabilitation, and therapy in prisons are viewed through a gendered lens. During the 1990s, the therapeutic communities and boot camp program became common forms of rehabilitation in U.S. prisons. However, these programs are not equally well suited to males and females. Among other issues, women respond less positively to confrontation, a staple of both types of programs (Marcus-Mendoza, Klein-Saffran, & Lutze, 1998). Also, female prisoners tend to have health problems that may preclude their participation in physically demanding activities (Sharp, 2003). Finally, to increase the likelihood of successful reentry, motherhood must be taken into account. With two thirds of female prisoners mothers to minor children, it is readily apparent that this is a serious social issue.

As the field moved into a focus on the criminal justice system and its response to women, scholarship related to women working within that system began emerging as well. Both the need for more workers and the increasing number of female prisoners have contributed to an increase of women working in law enforcement, as attorneys, and in the corrections industry. The entire field of criminal justice has long been dominated by men, in part because most criminals were men. With the rapid increase in both feminist criminological scholarship and of female prisoners, there is a burgeoning body of work by feminist criminologists that takes a gendered approach to studying policing, corrections, and the law. This approach has primarily focused on two aspects of the gendered nature of criminal justice employment. First, it looks at how women and men differ in the practices of their jobs. Feminist criminology asks what characteristics women working in criminal justice bring to their jobs and how these impact their work. Second, some feminist scholars have examined the ways in which the structure of law enforcement, corrections, and courts continues to lead to gender inequality (Britton, 2000).

Feminist Criminology in the 21st Century

Gaining widespread acceptance of feminist criminological scholarship has been a daunting task. Given the fact that the field of criminology has been dominated by scholars who are more wed to mainstream theories and research, approaches challenging the mainstream perspective have met with disdain or simply with disinterest. This has led to considerable difficulty getting feminist scholarship published as well as marginalization of the work that has been published. Indeed, there was not even a session on women and crime at the annual American Criminology Society meetings until 1975.

Publication in criminology journals has also been difficult, and much feminist scholarship was relegated to

smaller, and not very prestigious, criminology journals. In 1989, the journal *Women & Criminal Justice* was launched, specifically devoted to the publication of scholarly research on all aspects of women's and girls' involvement in the criminal justice system. Then, in 1995, *Violence Against Women* was launched to publish peer-reviewed scholarship on gender-based violence and female victims. Since the early 1990s, a wide range of books about women, crime, and criminal justice have been published. In 2006, Sage Publications introduced the first issue of *Feminist Criminology*, the official publication of the Division on Women and Crime of the American Society of Criminology. This journal has taken a broad focus on feminist scholarship, publishing peer-reviewed articles on feminist criminological theories, female offending, victimization of women, and the treatment of women and girls in the justice systems.

Feminist Criminology From a Global Perspective

Feminist criminology has arguably had more impact outside of the United States than within. This is because of the focus on violence against women that is a hallmark of feminist criminology as well as a recognized problem internationally. Research has focused on the abuse of women in Muslim countries and in India, female circumcision/genital mutilation, and female infanticide, to name a few topics. Because international attention has been drawn to the plight of women and girls in various parts of the world, research that takes a feminist slant on women's victimization has been welcomed (Maidment, 2006). At the international level, considerable attention has been paid to the exploitation of women and girls in the global sex industry. In addition, feminist criminologists study the ways in which laws and criminal justice policies around the world may victimize women, sanctioning them for violating traditional gender norms, in particular in regard to sexuality. For example, in some Muslim countries, women who are raped may be viewed and treated as offenders instead of as victims because they have violated the expectations regarding women's sexuality.

Some feminist criminologists have recently argued that there has been a global backlash against feminist attempts to improve the situations of girls and women, not only in third world countries but also in the industrialized West. A 2008 issue of *Feminist Criminology* was devoted to articles on how crime and victimization initiatives by feminists have led to a countermovement.

Conclusion

Although progress in the publication of feminist scholarship has been made, it remains somewhat marginalized in the overall discipline. Not only do mainstream journals

publish only limited feminist scholarship, but also textbooks give scant attention to feminist criminological theory. Thus, new generations of criminologists are educated and yet given little if any information about feminist criminology. This is reflected in their research as well as in their teaching and mentoring of new scholars. The cycle therefore remains self-perpetuating, with new criminologists receiving scant education on feminist criminology (Renzetti, 1993).

However, feminist criminology remains alive and well. The Division on Women and Crime is one of the largest sections of the American Society of Criminology, several major publishers have book series focusing on women and crime, and new scholars continue to emerge. The Division on Women and Crime, which started with a small group of scholars in the mid-1980s, has now existed almost a quarter of a century, and feminist scholars have been recognized as Fellows by the American Society of Criminology. Current feminist criminological scholarship includes theory building and theory testing, as well as research on violence against women; women's crime; and women in the criminal justice system, both as offenders and workers. The defining characteristics of feminist criminology are the emphasis on how social structures affect men and women differently, the relationship between research and activism, and the interrelatedness between victimization and offending among women.

LABELING AND SYMBOLIC INTERACTION THEORIES

SEAN MADDAN

INEKE HAEN MARSHALL

Northeastern University

It is a fundamental fact that for an action or behavior to be considered a crime, there must be some law in place. For instance, in the Prohibition era it was illegal to possess, manufacture, or distribute alcohol. Up to this time point and after Prohibition had ended, individuals who possessed, manufactured, or distributed alcohol were thus deemed “criminal” by a society attempting to right its moral compass. The example of Prohibition highlights a key aspect of crime that had largely been neglected by criminologists: the reaction to criminal behavior. Although consensus criminology was concerned with the etiology of criminality, it did not confront the role of societal reaction on social control in the criminal process. *Labeling theory* was the first to address both individual criminality and the impact of social reaction on criminal behaviors.

Kobrin (1976, p. 245) wrote that labeling is an intrinsic feature of all human interaction. As such, labeling theorists argue that a complete picture of crime or deviance cannot be attained by merely examining offenders and their characteristics; instead, a complete picture of deviance must also reveal societal reactions to incidents of rule-breaking. In line with symbolic interactionism, labeling theorists state that the reaction of the society, the community, or a social group will affect the rule-breaker in one critical way: A person labeled as a deviant may accept that deviant label by coming to view himself or herself as a deviant (i.e., internalizing the label) and then engaging in further behavior that

is both consistent with the label and the way in which the label was applied. This—the creation of additional deviance and criminality because of the application of a deviant label—is the central proposition of the labeling perspective.

The labeling perspective was developed over many years by a number of different social scientists (Becker, 1963; Cohen, 1995; Kitsuse, 1962; Lemert, 1951, 1967; Tannenbaum, 1938). This chapter examines the evolution of the labeling perspective and its contributions to the field of criminology.

The Labeling Perspective

In the early 20th century, the Chicago School of sociology transformed the landscape of sociology and set the standard for future criminologists. Two primary lines of inquiry came from this school: (1) human ecology and (2) symbolic interactionism. The different assumptions that underlie each of these theoretical models and the different focuses of each (the macro vs. the micro, respectively) would lead each theory to grow in its own directions. Human ecology would be applied to crime almost immediately in the form of social disorganization research, but it would not be until the 1960s that research applying symbolic interaction theory to criminality would occur in the form of the labeling theory.

Symbolic Interaction

The labeling perspective has its origins in the work of Mead and Cooley in the sociological theory of *symbolic interactionism*. Mead (1934) believed that the self arose through social processes, or social experiences, which involved play, game, and the generalized other. A person's self is generated when an individual takes the attitudes of other people in the group around him or her (whom Mead called the *generalized other*) and superimposes those attitudes upon behavioral patterns; thus, a person will generally behave in a manner that is consistent with the way in which that person believes others view him or her. Mead differentiated between the "me" and the "I," and Cooley (1926) referred to this process as the *looking-glass self*, which is a reference to the socially shaped self.

This process is not a static one; instead, it is a dynamic process of the individual "reacting back against society," which in turn is constantly reacting to the individual (Mead, 1977, p. 235). In this way, an individual will behave in a manner that is consistent with others' beliefs and expectations. Human behavior, then, revolves around the meanings of things and situations; the interpretation of these meanings through interactions with others; and the interpretive process an individual undergoes concerning interactions, both present and past (Blumer, 1969). Mead (1977) viewed this role taking as the foundation for social control (formal and informal). This two-way, symbolic interaction between the self and society forms the foundation of labeling theory.

Labeling Precursors

Although the ideas inherent in symbolic interaction work are at the core of the labeling perspective, it was Tannenbaum (1938) who first suggested their application to criminal behavior. In his discussion of a mostly subcultural theory of crime, Tannenbaum introduced the concept of the "dramatization of evil." As he argued, "The dramatization of the 'evil' which separates the child out of his group for specialized treatment plays a greater role in making the criminal than perhaps any other experience" (p. 19).

When a child commits a deviant or criminal act, this child is segregated from other children. A child who has come to the attention of the neighborhood or the criminal justice system has thus been "tagged." Tannenbaum (1938) provided the following description:

[The entire] process of making the criminal is a process of tagging, defining, identifying, segregating, describing, emphasizing, making conscious and self-conscious; it becomes a way of stimulating, suggesting, emphasizing, and evoking the very traits that are complained of. (p. 19)

The person thus takes on the characteristic of the so-called tag. The "evil" that is trying to be contained by the criminal justice system is then further exacerbated. This was the

first call for the deinstitutionalization of certain types of juvenile offenders.

As mentioned earlier, though, Tannenbaum (1938) was actually presenting his labeling approach through the framework of a subcultural theory of criminality. Tannenbaum noted that the isolation that ensues from a tag would lead an individual "into companionship with other children similarly defined, and the gang becomes his/her means of escape" (p. 20). Goffman (1963) later argued that people who have a "particular stigma tend to have similar learning experiences . . . a similar moral career" (p. 32). Tannenbaum's policy arguments, based on the dramatization of evil, did not focus on individual offenders but instead attacked whole groups of offenders in an effort to change attitudes and ideals.

Lemert (1967) was the next to explore the intricate web of the self, society, and deviance. He introduced the concepts of *societal reaction* (1951) and *primary* and *secondary deviance* (1967). Lemert (1967) used the socio-psychological concepts of primary and secondary deviance to "distinguish between original and effective causes of deviant attributes and actions which are associated with physical defects and incapacity, crime, and mental disorders" (p. 40). He argued that primary deviance arose from a variety of social, psychological, cultural, and physiological processes.

Primary deviance consists of "initial acts of norm violations or crimes that have very little influence on the actor and can be quickly forgotten" (Cao, 2004, p. 135). Primary deviants undergo no change in their psychological makeup or in the way they act as members of society (Beirne & Messerschmidt, 2000, p. 182). When they are apprehended, however, primary deviants suffer a variety of consequences, many of which focus on the application to them of such labels as sick, criminal, insane, and so on (Beirne & Messerschmidt, 2000, p. 182). Thus, secondary deviance is caused by the way in which society reacts to some of the people who engage in primary deviance. *Secondary deviance* "refers to a special class of socially defined responses which people make to problems created by the social reaction to deviance" (Lemert, 1967, p. 40). Secondary deviance occurs when the individual reorganizes his or her personality around the consequences of the deviant act and to persistent forms of deviance around which people organize their lives (Cao, 2004, p. 135).

Secondary deviance is promoted through an internal process of normalization of behavior and a lack of social controls; this process creates, maintains, and intensifies stigmas that include invidious labels, marks, or publicly disseminated information (Goffman, 1963), which are akin to Tannenbaum's (1938) "tags." The drug experimenter becomes an addict; the recreational drinker becomes an alcoholic; the joy rider a car thief. As the society begins to recognize and sanction these behaviors, the application of the labels increases, or *amplifies*, instead of decreases, the act. Lemert's (1967) concept of secondary

deviance goes to the heart of labeling theory: deviance as identity transformation.

In an immediate precursor to Becker's (1963) formulation of the labeling perspective, Kitsuse (1962) proposed a shift in "focus of theory and research from the forms of deviant behavior to the processes by which persons come to be defined as deviants by others" (p. 248). In his examination of homosexuality, Kitsuse collected data that suggested that the critical feature of the "deviant defining process" is not the actual individual's behavior, but rather the interpretations other people have of those behaviors. Kitsuse concluded that criminological theory must contain not only propositions pertaining to behavior but also concepts relating to the reaction to behavior.

Becker's Labeling Theory

Tannenbaum, Lemert, and Kitsuse had discussed important concepts in labeling and stigmatization, but the labeling approach was more systematically refined with the work of Becker (1963) on societal "outsiders." Becker argued that when a "rule is enforced, the person who is supposed to have broken it may be seen as a special kind of person . . . an outsider" (p. 1). Noticing, as Kitsuse (1962) had, that criminologists had focused primarily on deviant characteristics and had largely ignored the role of societal judgment in the study of deviance, Becker (1963) urged for the inclusion of society's reaction to deviant phenomena:

Social groups create deviance by applying those rules to particular people and labeling them as outsiders. From this point of view, deviance is not a quality of the act the person commits, but rather a consequence of the application by others of rules and sanctions to an offender. The deviant is one to whom that label has successfully been applied; deviant behavior is behavior that people so label. (p. 9)

This is the central proposition of the labeling perspective. To add to this, Becker (1963) also discussed other concepts of key importance for labeling theorists.

A label, or a stigma (Goffman, 1963), Becker (1963) contended, will vary because of certain theoretical concepts. First, the type of individuals who are labeled as deviant vary over time; for instance, individuals who were arrested for bootlegging in the Prohibition era would not be arrested today. Second, the degree to which an individual is considered deviant also depends on who commits the act and who has been victimized. A prime example is the treatment of white-collar and street-level offenders: Whereas street-level offenders usually will be processed through the criminal justice system if caught, white-collar criminals may be processed through criminal, administrative, or civil channels. Who commits the act and who is hurt will determine the extent and type of formal intervention and of the label. Finally, the term *outsider* may apply to the people who create the rules by individuals who are

breaking those rules. The rule makers can be outsiders to the so-called "deviant" group.

In his discussion of the labeling perspective, Becker (1963) identified four types of deviants: (1) falsely accused, (2) conformist, (3) pure deviant, and (4) secret deviant. The falsely accused deviant is the individual who receives a "bum rap," someone who has not broken any rules and yet is labeled. The conformist is someone who does not break rules and is not labeled. The pure deviant is someone who breaks rules and is so labeled. The secret deviant, which is discussed more later in this chapter, is the individual who engages in rule-breaking but is not labeled.

Because the idea of labeling is intertwined with the idea of secondary deviance (Lemert, 1967), Becker (1963) also discussed the *deviant career*, which begins with the commission of a deviant or criminal act. If a label is applied and is internalized by the individual, secondary deviance may ensue. Becker argued that research should focus on individuals who have engaged in at least one criminal act but have failed to become adult criminals as well as those offenders who continue criminality over time.

Becker (1963) later argued that he never thought he had set down the basis for a formal theory in his book, *Outsiders*; he merely wanted to enlarge the field of study for students of deviance. Becker suggested that secondary deviance should not be the main focus of labeling researchers; instead, the process of action–reaction–counterreaction was the most important aspect of the labeling approach. Becker noted that the labeling perspective was also not as consumed with the label as critics have argued. In a later interview, Becker (quoted in Debro, 1970) argued that the inclusion of societal reactions to deviance stemmed from his sociological past: "If we study a hospital . . . we study doctors, patients, nurses, aides, and so on. We may focus on one category of people, but we know that the actions of the others are important as well" (p. 166). Thus, the focus on only the offender in criminological theory is an incomplete picture of the entire criminal event; society's views and opinions must be taken into account.

Contemporary Labeling Extensions

Since Becker's (1963) original statements on the labeling perspective, others have added to the fragmented conceptualization of this theoretical model. Schur (1971) contributed to the labeling theory by conceptualizing other important ideas, such as the role of *stereotyping*. Schur argued that stereotyping has a dual role in society. First, stereotypes help individuals in complex interactions to classify the expectations of others' behaviors and the actual behavior of others. Second, stereotyping frequently involves the potential for individual reactions based on inaccurate assessments. Just because a stereotype (i.e., a label) is applied incorrectly, that does not mean that it affects the stereotyped individual any less.

Retrospective interpretation is another concept key to the study of labeling, according to Schur (1971). Retrospective interpretations involve the “mechanisms by which reactors come to view deviators in a new light” (Schur, 1971, p. 52). Mechanisms can range from something as simple as gossip to something as complex as a criminal trial. Negotiation and bargaining are important concepts in that they are the methods by which moral entrepreneurs and rulemakers assert labels; examples include the plea-bargaining process in criminal trials and lobbyists who influence legislators. Finally, Schur discussed *role engulfment*, or the process by which an individual takes a label and fully internalizes it, thus becoming the individual the label implies. This concept includes accepting the deviant identity or disavowing the deviant identity, or the joining of a deviant subculture by the labeled individual, as in Tannenbaum’s (1938) original formulation of the “dramatization of evil.” Role engulfment is hence the end result of the labeling process resulting in behavior based on internalization of the label.

Cohen (1995) argued that the “student of deviance must question and not take for granted the labeling by society or certain powerful groups in society of certain behaviors as deviant or problematic” (p. 211). Cohen’s contribution to labeling theory was in regard to the concept of the amplification of deviance by deviants and deviant groups. Amplification was not only mediated by face-to-face contact of individuals or by gossip but also was related to media depictions of deviance, because the mass media are a prime source of information about the normative contours of society. Cohen argued that society reacts to episodes of deviance on the basis of “information about that particular class of phenomenon, individual tolerance levels of an indicated behavior, and direct experience” (p. 215). So, amplification of deviance can occur from either the labeled or the labeler’s point of view.

In 1989, Paternoster and Iovanni explicitly formulated the propositions of the labeling perspective. In an effort to stimulate a new era of inquiry under the labeling perspective, they identified the four conceptual areas that must be evaluated to support a successful labeling theory: (1) the role of political/economic power in creating delinquency statuses; (2) the influence of extralegal attributes in determining who is labeled; (3) the contribution of social and physical attributes in determining face-to-face encounters; and (4) the possibility that the experience of being labeled by social control agencies may result in an alteration of personal identity, an exclusion from the normal routines of everyday life, and greater involvement with delinquency (p. 363).

A new focus for the labeling perspective in the 1990s was the change from studying formal labels to studying labels that are applied informally. *Formal labels* come from the reactions by officials of the criminal justice system to the behaviors of individuals (Triplett & Jarjoura, 1994, p. 243). *Informal labels*, on the other hand, are an attempt to “characterize a person as a given ‘type’ . . . by persons who are not acting as official social control agents,

and in social situations that are not formal social control ‘ceremonies’ ” (Paternoster & Triplett, 1988, p. 597). The informal label is associated with the concept of stereotype.

Although the *sociopsychological* effects of being labeled remain a central tenet of the labeling perspective, there is a growing interest in the effects that a formal criminal label may have on the legitimate *opportunities* (i.e., education, jobs, marriage) available to a formally labeled individual. Becker (1963) already hinted at this when he discussed the importance of the deviant subculture (i.e., once a person is submerged in a deviant subculture, associations and contacts with the nondeviant world diminish or are closed completely). More recently, the effect of a criminal conviction (or prison sentence) on an individual’s subsequent life course has become a focus of study. So, it seems that the sociopsychological effect on later life opportunities has become less crucial to study than the detrimental effect of a formal label (conviction or prison sentence) on later life opportunities.

The labeling theoretical model was generated over a large part of the 20th century. The way in which it was constructed, by myriad different sociologists, criminologists, and empirical researchers, has resulted in a fragmented theoretical model, with concepts added here and there or propositions being elaborated upon, here and there. The fragmented tapestry that is the labeling perspective, as well as the inherent attack on offender-oriented criminological theory by labeling theorists, has exposed it to a great deal of criticism and counterattack. The next section explores the primary lines of criticism that have been leveled against the labeling perspective.

Criticisms of the Labeling Perspective

Many criticisms have been leveled against the labeling perspective by criminologists who looked at labeling as an attack on prior theoretical thought. Labeling theory has been criticized as being too simplistic: The label affects self-concept, which leads to a change in self-concept, and this change in self-concept leads to a change in behavior (Wellford, 1975, p. 342). The labeling perspective has been argued to be nothing more than a small part of a much larger overall theory. This section explores both the theoretical and empirical shortcomings of the labeling perspective that have pervaded the area.

Early Theoretical Critiques

One of the first criticisms of the labeling perspective was presented by Gibbs (1966), who argued that there were several flaws in the labeling theory at that time, the most critical being that labeling theory puts the focus on the reaction to a type of behavior. This means that the deviant act is external to the actor and the act. In essence, it does not matter that the individual engaged in some deviant or criminal activity, only that there was some kind of reaction

from society. Only when a reaction is of a certain kind or level will there exist a deviant act. This is problematic for labeling theory in that clearly there has to be a rule-breaking act for a public or a criminal justice system response to occur in most cases. The response of labeling theorists to this critique has been simply to argue that they do not necessarily deny the significance of understanding the causes of initial deviance or rule-breaking but that their main interest happens to be on the role of the social responses to rule-breaking.

Akers (1967) outlined a different problem with the labeling perspective. According to Akers, "We still do not know very much about even the official distribution and variations in rates of some kinds of deviance and are practically ignorant of the true distribution of nearly every type of deviant behavior" (p. 459). In terms of the labeling approach, we still do not know very much about the true extent of rule-breaking. Because we do not know a lot about rule-breaking, how can we expect to be able to study the social response to rule-breaking, or so the critique goes.

Lemert (1974), one of the foremost labeling theorists, argued that the labeling perspective lacked discussion on the amount of consensus or dissent that exists in societal reactions, which makes it extremely difficult to study the societal reaction to deviance. In other words, different people will react differently to different types of crime. Rules of reaction and labeling appear to be automatically agreed on in the literature, especially in terms of personal, violent crime. In terms of lesser crimes, especially victimless crimes, people will behave differently in their reactions based on personal experience and beliefs.

A second line of criticism deals with the nature of societal reaction across different societies. According to Gibbs (1966), it was unclear whether Becker (1963) was pursuing a theory of deviant behavior or a theory about reactions to deviance. If the reaction is the key to deviant behavior, the implication is that deviance would not change across different societies in the world; that is, definitions of criminal activity (both social and legal) would be constant across all countries and societies. However, this is not the case. Many examples of this can be seen in a comparison of different countries' legal statutes; one example would be the fact that marijuana is illegal in America but legal in Amsterdam (Becker, 1963). Hence, there is a difference in the societal reactions between these two countries in their definition of marijuana use as a deviant/criminal behavior. Lemert (1974, p. 12) observed that the labeling perspective does not fully explain the process in which a society engages when reacting to behavior; a reaction may identify a deviant act, but it does not explain why the behavior is considered deviant.

Akers (1967) wrote that another problem with the labeling perspective was that labels do not explain the first deviant act, or the rule-breaking. Some rule-breaking has to precede deviant labels: Social definitions do not occur in a vacuum; they are mutually interactive. This could be, as Wellford (1975) contended, that the first assumption of the labeling perspective indicates that no act is intrinsically

criminal. Although there is a great deal of difference across countries and societies in how criminal behaviors are viewed and treated, most societies have found it important to control certain kinds of behavior; for instance, across countries and cultures, murder, robbery, burglary, and larceny have been found to be important crimes to control (Wellford, 1975, p. 335).

Another theoretical criticism of the labeling perspective has come from criminologists who recognize the link between labeling and deterrence. Tittle (1975) argued that the labeling perspective does not address instances in which labeling will actually deter the deviant career by inhibiting deviance. Thorsell and Klemke (1972) contended that it is difficult to study the labeling approach without giving thought to the deterrence model. Deterrence implies that sanctions will deter offenders from engaging in further criminal behavior through a process of rational choice, whereby an offender will weigh the cost and benefits of any future offending through the lens of the previous punishment (Bowers & Salem, 1972, p. 428). According to Thomas and Bishop (1984, p. 1223), both models adopt a social psychological level of analysis, apply to the way sanctions affect offenders, are concerned with formal and informal sanctions, and have ramifications for social policy. Indeed, one of the most intriguing questions remains whether the person on whom the label "criminal" is conferred is likely to be propelled into more crime or deterred from future criminal behavior (Paternoster & Iovanni, 1989).

Finally, Gibbs (1966) presented a purely semantic theoretical argument against the labeling perspective. According to Gibbs, Becker's (1963) discussion of the secret deviant is a contradiction in terms; if deviance is the end result of a reaction, the secret deviant could not be a deviant at all. This secret deviant would never be labeled at all and hence would never be a deviant.

Early Empirical Critiques

In his examination of the assumptions of the labeling perspective, Hagan (1973) focused on the assumption that pertained to another's reaction leading to an intensification of a behavior (i.e., secondary deviance). Hagan argued that there was a large empirical gulf between the society that reacts to a behavior (labelers) and the individual who is labeled; in the research, there is only a focus on one or the other in specific studies: either the labeled individual or the society/group that is labeling. Hagan concluded that these two concepts should be studied in concert.

Tittle (1975) noted another empirical shortcoming with the labeling perspective: There are very few available data sources capable of capturing labeling and its effects on criminality. The data that are available, recidivism data in most cases, are difficult to obtain and do not allow a straightforward assessment. Because of the nature of recidivism data (i.e., they apply only to offenders who have been rearrested, reconvicted, reincarcerated, or some combination of these three), they are inappropriate to study the full effects of

labeling. Offenders could still be recidivating (the dark figure of crime). The key in this argument is that only individuals who are rearrested are captured in these data; thus, anyone who is reoffending and does not again come under the purview of the criminal justice system would appear as nonrecidivating. Although recidivism data are difficult to marshal in labeling research, Tittle argued that the findings from studies that have used these types of data indicate weak results for the labeling perspective. Because of the combination of the lack of available data and the persistent weak findings of recidivism data, Tittle concluded that this method of testing the labeling perspective was not a clear-cut resolution.

Mankoff (1971) argued that labeling theorists have failed to conceptually or empirically specify which sanctions lead to continued deviance and what severity of sanction is required to produce career deviance. A great deal of the research on labeling has examined individuals with mental impairments and other physical impairments/stigmas (ascriptive rule-breaking). Criminology is more concerned with *achieved rule-breaking*, which is an activity on the part of the rule-breaker. Mankoff's analysis suggests that the labeling perspective is not as useful in evaluating achieved rule-breaking as it is in examining ascriptive rule-breaking. As well, Mankoff urged criminologists to conceptualize adequately self-labels and the effects inherent in such labeling processes.

Another empirical criticism was presented by Hirschi (1975), who contended that much research actually refutes propositions of the labeling approach. One primary policy initiative that has come from the labeling literature is the deinstitutionalization of juvenile offenders. Hirschi argued that the majority of the research on the treatment of juvenile delinquents generally indicates either minor effects or no effects on future criminality one way or the other; instead, the results indicate a spontaneous remission in the majority of the cases. These empirical results are in contrast to labeling theory propositions.

Gibbs's (1966) assertions—that labeling theorists have failed to stipulate what kind of reaction identifies, or promulgates, deviant behavior and that they have not fully conceptualized all of the components of a full labeling theory—are still true today. Although this section has explored problems with the labeling approach in terms of both theoretical development and methodological questions, there still is a good deal of research that has explored the links between labeling and deviance that indicates that labeling does indeed have some effect. This suggests that the labeling perspective does have some merit. The next section examines research that has evaluated the labeling perspective.

Labeling Research

Although there has been a great deal of academic bantering over the merits of the labeling perspective, criminologists

have managed to amass much evidence to support the effect of labels on criminality. Although they acknowledge that some of this research has suffered from methodological and conceptual shortcomings, the majority of the findings indicate that individual labels have moderate to strong effects on an individual's engagement in secondary deviance or crime. Although the effect of labeling on an individual varies across studies, what is not in question is that labels do account for some of the variance in predicting continued criminality. This review of labeling research focuses on empiricism that examines the effects of labeling on secondary deviance only.

Foster, Dinitz, and Reckless (1972) argued that it is very difficult to measure all the variables associated with deviant behavior as well as all of the variables associated with the societal reactions to such behavior. In their longitudinal study, Foster et al. found that, according to the perceptions of the 196 boys in the study, "the extent of perceived stigmatization and social liability that follows police or court intervention seems to be overestimated in the labeling hypothesis" (p. 62). Thus, at the time of intervention the boys in this sample did not perceive a stigma. Boys with previous experience with the criminal justice system will perceive more of a stigma than first-time offenders; Foster et al. referred to this as a *cumulative effect*. On the whole, though, Foster et al. found little support for the labeling perspective.

Farrington (1977) examined the effects of public labeling. Hypothesizing that individuals who are publicly labeled will increase their deviant behavior, Farrington examined data from the Cambridge Study in Delinquent Development. Public labeling was defined as court convictions. Deviant behavior and labels were measured through self-report data. This research had two significant findings. First, public labeling did lead to increased deviance; second, repeated labeling of an individual led to greater deviance amplification. Thus, Farrington's findings were consistent with the labeling perspective.

Link and colleagues (Link, Cullen, Struening, Shrout, & Dohrenwend, 1989) examined the effect of labels on individuals with mental disorders and the social support networks of such individuals. Studying 164 patients and 429 community residents through surveys, these researchers found that, primarily because of their stigmatized status, individuals with mental disorders are devalued and discriminated against. Link et al. (1989) contended that in "the course of being socialized, individuals develop negative conceptions of what it means to be a mental patient and thus form beliefs about how others will view and then treat someone in that status" (p. 419). Treatment and time spent in mental clinics help to solidify labels, helping individuals to more readily internalize the label. Labels appeared to affect mental patients even independent of psychopathology and biological variables.

Link et al.'s (1989) research is consistent with Hirschi's (1969) *social bond theory*, according to which individuals who are more attached to a social network are more likely

to be concerned with the stigma. Through this concern with stigma, these individuals will be less likely to engage in activities characteristic of emotional disturbance, such as obsessive-compulsive behaviors and manic-depressive behaviors. The stigma of mental health patients does not affect support networks, either positively or negatively. This could suggest that the effects of labeling decrease over time. Link et al.'s findings with regard to mental illness show general support for the labeling perspective.

Kaplan and Johnson (1991) argued that labeling theorists are particularly interested in the relationship between negative social sanctions for deviant behavior and the escalation of that deviant behavior. They argued that this relationship might be mediated by deviant peer associations. In their survey analysis of students in 36 junior high schools in Houston, Texas, Kaplan and Johnson estimated a structural equation model to examine the effects of negative sanctions (suspension, expulsion, contact with the criminal justice system, and any office punishment) on the escalation of deviant behavior. Their results illustrated not only that there was a direct effect of negative sanctions on later deviance but also that the presence of a deviant peer group played a mediating role for individuals who had been negatively sanctioned. Although Kaplan and Johnson concluded that labeling is an integral part of further criminality, they argued that this is only one of the many factors that had significant effects in the model (they found support for the deterrence hypothesis as well).

Ward and Tittle (1993) examined the relationship between the deterrence and labeling hypotheses. As has been seen in some of the prior research on labeling theory, deterrence and labeling are two interrelated ideas. Sanctions may increase one's perceptions of risk and can help deter the individual from breaking the rules; however, sanctions may lead to more deviance by increasing a commitment to a deviant identity, which is the premise of symbolic interaction and labeling theories (Ward & Tittle, 1993, p. 45). To study the relationship between these two rival ideas, Ward and Tittle analyzed 390 senior and junior students in a university through a telephone survey instrument. Regression analyses indicated that there was no direct effect of labeling on further deviance. Although sanctions had a significant effect on labeling, labeling was directly linked to the formation of a negative self-appraisal; negative self-appraisal did exert a direct influence on secondary deviance. Ward and Tittle concluded that their results supported labeling theory better than deterrence theory. However, labeling is not a necessary condition for secondary deviance, because initial deviance and sanctions had strong direct effects on secondary deviance.

Triplett and Jarjoura (1994) focused on the informal labeling of deviants. Integrating the social control and labeling approaches, they used data from the National Youth Survey to study the effects of informal labeling on both primary and secondary deviance. Triplett and Jarjoura (p. 257) found that labeling theory could play some role in the initiation of deviance; the perception of

being labeled by parents significantly affected a youth's attachment to school. School attachment was heavily related to both peer association and delinquent beliefs by youth. As with Ward and Tittle's (1993) research, labeling had no direct impact on deviance in general but instead was mediated by other variables. One of Triplett and Jarjoura's other significant findings was that negative parental labels lead children to break ties with schools and increase involvement with delinquent peer groups; this involvement led to the adoption of delinquent beliefs by the labeled child.

Heimer and Matsueda (1994) used data from the National Youth Survey to explore the effects of symbolic interaction (role taking and role commitment) on delinquency. The results of their structural equation model in regard to delinquency yielded four key findings. First, structural and neighborhood variables had indirect effects on delinquency through role-taking variables. Second, delinquency is also a result of differential association variables, such as having delinquent peers and learning attitudes about the legal code. Third, their research showed only minimal support for the impact of labels on secondary deviance. Fourth, in line with social disorganization and social control theories, strong ties to conventional institutions affect delinquency as well. In this research, labeling played a very minor role in delinquency.

Following up on previous research of students in 36 high schools in Texas, Kaplan and Damphousse (1997) examined the interconnection of negative social sanctions, self-derogation (the negative affect evoked in individuals associated with personal qualities, achievements, and behavior), and deviance. Their analysis revealed an interaction between negative self-attitudes and negative social sanctions; this interaction directly affected deviance. Kaplan and Damphousse concluded that negative social sanctions have a positive effect on later deviance and that self-derogation moderated this effect. As with the previous research, this study found support for the labeling perspective.

Bernburg and Krohn (2003), in a more recent exploration of the labeling perspective, examined how labels lead to social exclusion and hence blocked access to structured opportunities. According to Bernburg and Krohn, "The social marginalization caused by stigma attached to the deviant label raises the likelihood of subsequent . . . involvement in deviant activity" (p. 1290). On the basis of time series data from the Rochester Youth Development Study, Bernburg and Krohn examined the effect of police and juvenile justice interventions on 1,000 students' (in the seventh and eighth grades in 1987–1988) criminality in young adulthood in conjunction with other contextual and control variables. Although the overall models yielded small effects, some of the variables showed highly significant results. In particular, Bernburg and Krohn found that official intervention decreased the odds of graduation from high school. The lack of educational attainment had a direct impact on employment, which serves as an intermediary to adult crime. Bernburg and Krohn's research indicates some support for the labeling perspective.

Although much of labeling theory research focuses on the effects of formal labels, some research has analyzed the effects of informal (i.e., parental) labeling, in particular on young people. Matsueda (1992) examined the effects of parental labeling on delinquency in attempting to specify a model of symbolic interaction. Matsueda defined the unit of analysis as the *transaction*, which consists of an interaction between two or more individuals. This transaction is what results in a potential label for deviants. Using data from the National Youth Survey, Matsueda used structural equation modeling to explore the labeling process. Like Triplett and Jarjoura (1994), Matsueda found that negative parental labels were associated (indirectly, through prior delinquency) with delinquents, non-whites, and urban dwellers; that is, labels affected delinquency. Although youth's self-appraisals are strongly influenced by parental appraisals, this relationship is mediated by an individual's delinquent self-appraisal; thus, individuals who view themselves as delinquent are more likely to be affected by parental views of behavior.

Liu (2000) examined whether informal labeling by significant others predicted youth involvement in crime and in which social contexts (with a focus on peer groups and learning theory type variables) the labeling process would lead to criminality or deviance. Liu found that there was a direct effect of parental labeling on a juvenile's propensity to engage in deviance. Liu also found that peer group attitudes and participation in delinquency modified the effects of parental labeling on delinquent acts; peer group activities would lead to delinquency regardless of the label supplied by parents. Liu's accounts thus give more importance to the learning theory variables in explaining criminality and continued delinquency.

Hypotheses have been formed that members of different races experience labels differentially (Paternoster & Iovanni, 1989). Adams, Johnson, and Evans (1998) examined the effects of deviant labels on members of different racial backgrounds. Using data from the National Youth Survey, Adams et al. found that members of ethnic-racial minority groups are more likely to be affected by informal labels (peer networks and community) and that whites are more likely to be affected by formal labels (criminal justice system). Although minorities are affected weakly by formal labeling processes, Adams et al. argued that minorities may not view formal labelers as credible, because formal labels may come from racist attitudes or other beliefs of the labelers. This is consistent with Becker's (1963) arguments that the person who labels can be seen as the outsider.

Current labeling research has been expanded since its inception to include such topics as the role of economic and political power involved with labeling, the influence of extralegal attributes on label application, and the effect of social and physical traits on labeling. The majority of current research on labeling theory focuses on career criminal research and life course theory. In this research, particular attention is paid to the effect of the label on future deviance/criminality. Examinations of societal

reactions to deviance have largely been relegated to studies pertaining to the social construction of social problems. Social construction research takes a particular social problem and applies content analysis to ascertain how the problem became a problem (or how society reacts to certain behaviors).

In sum, the vast majority of research on the labeling perspective indicates some level of support for this approach. The impact of a label on continued deviance and criminality is certain, but the question of the degree to which the label matters still warrants attention. Therefore, research on the labeling perspective will inevitably continue in the future, especially in regard to career criminal research.

Conclusion

Labeling theory argues that social groups create deviance by agreeing on rules and laws and by applying these laws to individuals. In this perspective, the reaction to criminal behavior is just as crucial to the study of crime as an individual criminal's behavior. The labeling perspective posits a dynamic process whereby an individual is labeled either a deviant or a criminal, internalizes that behavior by coming to view himself or herself as deviant or criminal, and then continues in behavior that is consistent with the applied label.

Labeling theory acts most effectively as a bridge between consensus theories of criminality (rational choice, social learning, social disorganization, strain, subculture, and control theories) and critical theories that examine the impact of social structures on criminality. This is a function that no other criminological theory can serve, and it illustrates the importance of this theory.

LIFE COURSE CRIMINOLOGY

WESLEY G. JENNINGS

University of Louisville

ALEX R. PIQUERO

University of Maryland

The relationship between age and crime has been among the most researched of all “facts” in criminology (Farrington, 1986a; Hirschi & Gottfredson, 1983). Furthermore, it also has been—and continues to be—one of the most contentious of all issues, with researchers expressing different views about its meaning and interpretation. More specifically, the robust nature of the relationship between age and crime gives rise to the question of whether the degree to which the *aggregate* pattern displayed in the age–crime curve (i.e., with crime rising to a peak in the late teens and then declining more or less in the early 20s) is more similar or different from the pattern of *individual* careers.

Acknowledging the long history of scholarly attention to understanding the age–crime curve, a substantial amount of information has been generated with regard to the onset, persistence, and desistance associated with criminal offending over the life course. In the same vein, this rich research has fostered the development of theories of crime that have been proposed across a number of social science disciplines. The commonality that is evident across these theories is that they seek to explain the fluctuations in criminal activity over the life course as well as offer assumptions as to how and why individuals may vary in their involvement in crime and deviance across key developmental phases of the life course.

The purpose of this chapter is to provide readers with an overview of what has been termed *life course criminology*. The chapter begins with a brief overview of the criminal career framework and provides some empirical evidence on what is known about criminal offending over the life course based on the research findings gleaned from some of the most notable studies in this area. This section is followed by a discussion of the origin of the life course paradigm as we know it today, including its roots in sociology and psychology, which subsequently led to the emergence of the developmental/life course criminology (DLC) paradigm in criminology in particular. Following a review of several key DLC theories, this chapter concludes with a brief presentation of the gaps in the current DLC literature and offers several suggestions of where future research in this area should proceed.

Criminal Careers

To understand what crime over the life course actually means for research and practical purposes, it is important to become familiar with the criminal career terminology. In its most rudimentary form, a *criminal career* is the “characterization of the longitudinal sequence of crimes

Authors' Note: Portions of this chapter are excerpted from *Key Issues in Criminal Career Research: New Analyses of the Cambridge Study in Delinquent Development* by Alex R. Piquero, David P. Farrington, and Alfred Blumstein. Copyright © 2007 Alex R. Piquero, David P. Farrington, and Alfred Blumstein. Reprinted with the permission of Cambridge University Press.

committed by an individual offender” (Blumstein, Cohen, Roth, & Visser, 1986, p. 12). As the word *longitudinal* implies, there is an inherent time dimension to criminal careers. Furthermore, this suggests that there are identifiable start and end points that allow researchers to chart out an individual’s criminal career length.

The criminal career paradigm acknowledges that certain individuals start their criminal activity at one particular age, continue to commit various crimes for some period of time, and then essentially quit offending. Considering this assumption, the criminal career framework suggests the need to examine causes and correlates related to why and when individuals start offending (onset), why and how they continue offending (persistence), why and whether offending becomes more frequent or serious (escalation) or specialized, and why and when people stop offending (desistance).

Although one of the earliest criminal career studies was the qualitative depiction of delinquency presented by Clifford Shaw (1930) in *The Jack Roller*, criminal career research soon turned noticeably quantitative. Sheldon Glueck and Eleanor Glueck’s pioneering work, *500 Criminal Careers* (1930), and a follow-up study entitled *Unraveling Juvenile Delinquency* (1950) provided criminologists with the most definitive and detailed source on the correlates of crime and how crime fluctuated over the life course among 500 delinquent and 500 matched control youth growing up in Boston. Not only was the Gluecks’s study unique and rigorous in its methodological design, but also the data provided by the Gluecks were considerably comprehensive. For instance, the Gluecks collected a wealth of information from self-reports (participant, parent, and teacher interviews) and gathered data from official records (police, court, and corrections). Thus, the richness of these data was unprecedented in its time and served as one of the key sources for criminological theorizing for some time. It continues to inform criminological theory today.

Quite some time after the Gluecks’s pioneering efforts, Marvin Wolfgang and his colleagues successfully completed one of the most well-known studies to date of the longitudinal progression of crime over the life course. This research, referred to as the *Philadelphia Birth Cohort Study* (Wolfgang, Figlio, & Sellin, 1972), was a retrospective study of criminal activity among all 9,945 males born in the city of Philadelphia (with continual residence through age 17) in 1945. Although the study was limited in that it contained only basic demographic information and relied solely on official sources of data, two of its key findings were groundbreaking at the time. The first important finding was that nearly one third of the cohort had an official police contact by age 17, and most of these offenders were “one-timers” in that they did not accumulate another police contact after their initial offense. Second, and perhaps more important, Wolfgang et al. discovered that only 6% of the cohort and 18% of the cohort’s offenders were responsible for committing roughly half of all the offenses and about two thirds all of the violent offenses. In a

10-year follow-up study of 10% of the original Philadelphia birth cohort, Wolfgang, Thornberry, and Figlio (1987) found that these chronic offenders had increased the seriousness of their offending into adulthood. In an effort to replicate and extend these research findings, Tracy, Wolfgang, and Figlio (1990) conducted the Second Philadelphia Birth Cohort Study, which was a retrospective study of the official records of more than 27,000 individuals who were born in Philadelphia in 1958 and socialized in the 1960s and 1970s. Although the prevalence of offending in general was similar to that of the first Philadelphia Birth Cohort Study, Tracy et al. found even higher rates of chronic offending among the members of the Second Philadelphia Birth Cohort. More specifically, they found that the chronic offenders represented 7% of the cohort and 23% of the offenders yet were responsible for committing 61% of all the offenses, including 60% of the homicides, 75% of the forcible rapes, 73% of the robberies, and 65% of the aggravated assaults.

The novel and influential findings generated from both the Gluecks’s and Wolfgang et al.’s birth cohort studies stimulated a series of other well-recognized longitudinal studies that have made notable contributions to the criminological literature in recent years. With some exceptions, a number of these studies are relatively recent, and thus not enough time has passed to enable tracking of these individuals into middle/late adulthood. However, there are two such examples of efforts that have been undertaken to follow participants from childhood into middle/late adulthood. Laub and Sampson (2003) are credited with the first of these efforts, wherein they conducted a qualitative and quantitative analysis of a follow-up of the Gluecks’s (1930) study (reviewed earlier) of the criminal careers of the 500 Boston-area male delinquents through age 70. In comparison, Piquero, Farrington, and Blumstein (2007) most recently presented the results of a thorough analysis of the criminal careers of 411 South London males from age 10 to 40 who participated in the Cambridge Study in Delinquent Development (West & Farrington, 1973).

It is important to note that Laub and Sampson’s (2003) follow-up study of the Boston delinquents is the longest longitudinal study of criminal activity in the field. In recognition of this, a series of key findings from their research efforts are worth highlighting. Although the results from a trajectory analysis suggested that there were six groups of individuals who demonstrated unique patterns of involvement in crime over the life course, the trajectory groups for the most part appeared to desist in middle/late adulthood, with virtually no group demonstrating continued involvement in crime at age 70. Although further trajectory analysis results disaggregated by crime type (property, violent, alcohol/drugs) revealed interesting similarities and differences compared with the aggregate trajectory analysis such that property crime trajectories mirrored the aggregate trajectories, violent crime trajectories appeared to peak later, and alcohol/drug trajectories seemed relatively stable throughout young and early/middle

adulthood, subsequent attempts to determine key risk/protective factors that distinguished trajectory groups from one another were not fruitful.

Nevertheless, as mentioned earlier, Laub and Sampson (2003) also incorporated a qualitative element into their research in that they conducted extensive interviews with 52 of the delinquent males. On the basis of the individual interviews, it appeared that criminal justice intervention was a risk factor for some and a deterrent for others—in other words, some of the respondents reported that their criminal justice involvement caused them to stop their offending, whereas others indicated that their criminal justice involvement increased/enhanced their continued participation in offending. Another key finding from Laub and Sampson's interviews of the Gluecks's (1930) participants was in regard to life transitions. Their qualitative analysis appeared to suggest that marriage was a key source of informal social control, or a turning point, in their lives that caused them to give up their involvement in crime.

As a point of comparison, Piquero et al.'s (2007) research represents the second study that involves long-term follow-up of individuals tracked from childhood into middle/late adulthood. In their analysis, Piquero et al. used data from the Cambridge Study in Delinquent Development (West & Farrington, 1973) to investigate and describe the offending patterns of 411 South London males who were first contacted at the ages of 8 through 10 in the early 1960s for participation in the study. The findings that emerged from Piquero et al.'s efforts were based on the official conviction records of the males at age 40 along with a series of self-reports of their involvement in criminal activity in order to gather information related to the progression of their offending over time.

A series of key findings from Piquero et al.'s (2007) analysis relate to each of the respective dimensions of criminal career research and have import for life course criminology. The first of these results is in regard to the prevalence of offending, the peak age of criminal activity, and the stability/variability of crime over the life course. Piquero et al. revealed that nearly 2 out of every 5 of the South London males (e.g., 40%) accumulated an official conviction for a crime at some point in their lives. However, it appeared that the prevalence of offending for the sample peaked in late adolescence, at approximately age 17. Furthermore, the results indicated that for the most part the frequency of offending tended to follow the prevalence (with violence being the exception) and that there was a considerable degree of stability in offending across age.

The next set of significant research findings germane to criminal career dimensions and life course criminology were onset and frequency and severity of offending, offense specialization, and career length. Regarding the relationship between onset age (the age at which an individual commits his or her first offense) and frequency of offending and severity of offending, Piquero et al. (2007) found that an early onset of offending was related to having a

more extensive criminal career as determined by accumulating numerous convictions, having a higher probability of participation in violence, demonstrating a longer criminal career, and displaying involvement in many different types of offenses. Furthermore, there was virtually no evidence of specialization in violence among the offenders from South London. In contrast, the results seem to suggest that involvement in violence was related to offending frequency such that individuals who were committing the greatest number of offenses were also those who were the most likely to have a violence conviction. Thus, violent offenders just tend to roll the dice more often. Turning toward career length, Piquero et al.'s results suggested that the average length of a criminal's career (measured as the time from first offense to the time at last offense) was 10 years and that there was a general decline in age for both residual career length and residual number of offenses.

The last two key findings from Piquero et al.'s (2007) analysis can be directly compared with the early criminal career research on chronic offenders and chronic offending (e.g., Wolfgang et al.'s [1972, 1987] studies) and Laub and Sampson's (2003) trajectory analysis with the Gluecks's (1930) data. Similar to the evidence described earlier in the discussion of Wolfgang et al.'s (1972, 1987) studies, Piquero et al.'s analysis of chronic offenders and chronic offending found that a small group of the males with five or more convictions was responsible for a significant amount of the sample's total convictions. At the same time, their analysis also indicated that the probability of recidivism after the fourth conviction was very similar thereafter, that is, 84.5%. Finally, whereas Laub and Sampson's trajectory analysis with the Gluecks's data revealed six trajectory groups through age 70, Piquero et al.'s trajectory analysis of the conviction records among the South London males suggested the presence of five distinct groups of offenders. Despite this difference, like Laub and Sampson's results, each of the trajectory groups identified in Piquero et al.'s analysis had unique shapes and levels of offending through age 40 and varied on several criminal career dimensions. In addition, Piquero et al. were also able to identify a set of environmental and individual risk factors that were able to distinguish membership in the five distinct trajectory groups.

The Life Course Paradigm

Running in parallel with these criminal careers studies, the fields of sociology and psychology have outlined a *life course paradigm*. The life course paradigm can be defined as a series of pathways throughout the developmental process in which there are varying age-dependent expectations and available options in an individual's decision-making process. These decisions, along with the natural course of life events, are seen to shape the trajectory of an individual's life and can be influenced by transitions and

turning points (Elder, 1985). Trajectories are viewed as pathways of development over the life span, such as work life, marriage, schooling, or involvement in crime. They are seen as long-term behavioral patterns that are marked by a sequence of life events and transitions. These transitions are then described as distinct life events that occur in shorter intervals that may alter an individual's behavioral trajectory (e.g., first job, first marriage, first child; Elder, 1985, pp. 31–32). According to Elder (1985, p. 32), the interlocking nature of trajectories and transitions may generate turning points or changes in the life course.

More recently, Sampson and Laub (1993) extended this framework by focusing on the strong association between childhood events and adulthood experiences and the idea that transitions can redirect an individual's life course behavioral pathway. They indicated that life course analysis focuses on the length, timing, and the order of significant life events (including crime) and their effect on future social development. Attention to the impact of life events is critical, because research has shown that committing a crime has a considerable behavioral influence on the likelihood of an individual committing crime in the future (for a review, see Nagin & Paternoster, 2000). Furthermore, Sampson and Laub (p. 303) focused on age-graded life transitions and argued that institutions of formal and informal social control matter and vary over the life course. They contended that age-graded informal social control is essential for promoting interpersonal bonds that link individuals to the larger social institutions in which they live (i.e., work, family, school). They also acknowledged that both continuity and within-individual changes do occur over time and that specific life transitions and other factors related to development may intervene in one's pathway of offending (Farrington, 1986b, referred to this as the *stepping-stone approach*). Ultimately, the life course paradigm is best summarized as "pathways through the age-differentiated life span," where age differentiation "is manifested in expectations and options that impinge on decision processes and the course of events that give shape to life stages, transitions, and turning points" (Sampson & Laub 1993, p. 8; see also Elder, 1985).

Life Course Criminology

In recognition of the robust relationship between age and crime, the importance of early influential criminal career research (Glueck & Glueck's [1930, 1950] and Wolfgang et al.'s [1972, 1987] studies) and the findings generated from recent efforts (Farrington, 2003; Blumstein et al., 1986; Laub & Sampson, 2003; Piquero et al., 2007), and appreciating the life course paradigm developed in sociology and psychology, there has emerged a subfield within criminology known as DLC criminology (Farrington, 2003).

Within criminology, the life course perspective is an effort to offer a comprehensive outlook to the study of

criminal activity because it considers the multitude of factors that affect offending across different time periods and contexts (Thornberry, 1997). One of the core assumptions of DLC theory is that changes with age and delinquency and criminal activity occur in an orderly way (Thornberry, 1997, p. 1), and some of the DLC theories that have begun to emerge from this perspective have in large part made an effort to not only document crime over the life course but also to more readily identify the key risk and protective factors associated with the onset, persistence, and desistance from criminal activity. Furthermore, these DLC theories have made efforts to integrate knowledge from other disciplines outside of criminology into their theoretical frameworks, most notably drawing from psychology, sociology, biology, and public health.

In general, DLC theory concentrates on three main issues: (1) the development of offending and antisocial behavior, (2) the effect of risk and protective factors at different ages on criminal activity at different ages, and (3) the effects of life events on the course of development and criminal activity throughout the life course (Farrington, 2003, p. 221). With regard to the first issue, empirical research has documented the progression of delinquency and criminal involvement over time (see, e.g., Tracy et al., 1990), but there is a general lack of available data that follows individuals from early on in life well into middle and/or late adulthood (for important exceptions, see Laub & Sampson, 2003; see also Piquero et al., 2007). Concerning the second issue, research is beginning to identify key risk and protective factors that have an impact on whether an individual becomes involved in crime in the first place and whether he or she continues to be involved in crime over the life course (see Hawkins & Catalano, 1992; Loeber & Farrington, 1998). Turning toward the final issue (as identified by Farrington, 2003), recent research evidence has suggested that several key life events, such as marriage and steady employment, not only appear to be related to participation in offending but also seem to be particularly important in the reduction of criminal activity and fostering desistance from crime in general (Farrington & West, 1993; Horney, Osgood, & Marshall, 1995; Laub, Nagin, & Sampson, 1998; Piquero, Brame, Mazzerole, & Haapanen, 2002). In contrast, additional research has shown that other life events, such as incarceration, are a risk factor for subsequent and continued involvement in criminal activity (Sampson & Laub, 1997).

In his review of DLC theory and research, Farrington (2003, pp. 223–224) identified 10 widely accepted conclusions about the development of criminal offending:

1. The prevalence of offending peaks in the late teenage years.
2. The peak age of onset of offending is between 8 and 14, and the peak age of desistance from offending is between 20 and 29.

3. An early age of onset predicts a relatively long criminal career duration.
4. There is marked continuity in offending and antisocial behavior from childhood to the teenage years and to adulthood.
5. A small fraction of the population (the chronic offenders) commits a large fraction of all crimes.
6. Offending is versatile rather than specialized.
7. The types of acts defined as offenses are elements of a larger syndrome of antisocial behavior.
8. Most offenses up to the late teenage years are committed with others, whereas most offenses from age 20 onward are committed alone.
9. The reasons given for offending up to the late teenage years are quite variable, including utilitarian reasons, for excitement or enjoyment, or because people get angry.
10. Different types of offenses tend to be first committed at distinctively different ages.

Considering this list of relatively undisputed truths about the development of criminal offending, it is also important to point out that the strength of the evidence for these truths does range considerably from relatively strong evidence to substantially strong evidence. Keeping this in mind, Farrington (2003, pp. 225–227) also described a series of issues in DLC criminology that are still points of contention to which DLC theories and research should attend. For instance, although the evidence is fairly robust with regard to the prevalence of offending peaking during late adolescence, the research is not as clear as to how an individual's frequency of offending fluctuates in any given year and whether seriousness escalates and de-escalates as a function of age. Furthermore, two related issues concern the relationship of early-onset offending with later-onset offending and chronic offending with less frequent offending. More specifically, it is not yet determined whether early-onset offenders are different in degree or kind from late-onset offenders or whether chronic offenders are merely distinguishable from less frequent offenders in the number of offenses committed or if their offense repertoires are in fact distinct from one another.

The last few contentious DLC issues (identified by Farrington, 2003) focus on escalation, risk and protective factors, and intermittency in criminal careers. First, the research is not clear on whether certain types of offenses act as precursor events or gateway offenses (or stepping stones) for other types of offenses. For instance, does burglary lead to later sexual offending? Second, although risk and protective factors for early-onset offending are well-known, the evidence is lacking on whether these factors are in fact causal or whether they are merely indicators of the same underlying construct. Finally, research should incorporate and seek to explain the possibility that intermittency in criminal careers affects their results. For example, all offenders do not necessarily start offending at one particular point in time, continue offending for some duration, completely quit (desist) at another particular point in

time, and never offend again. Instead, some offenders appear to desist for some period of time before restarting some years later, perhaps in response to some adverse life event such as losing a job, getting a divorce, or developing a substance abuse problem.

Acknowledging the current truths and points of contention in DLC research, the following section of this chapter highlights some of the key DLC theories and reviews their basic assumptions and expectations. The chapter concludes by offering some suggestions on where DLC theoretical development and modification and DLC empirical research should perhaps move toward in the future.

Developmental/Life Course Theory

As discussed in the previous section, criminology has witnessed a considerable degree of knowledge infused into its theorizing from other social science and related disciplines. This recent growth in interdisciplinary thought has likely had the largest effect on the origins of DLC theories. The following discussion reviews some of criminology's most recognizable DLC theories, with particular attention paid to those that have received a considerable amount of empirical research.

Similar to Moffitt's (1993) developmental taxonomy, Patterson and Yoerger's (1999) theory is also based on a two-group offending model: early-onset offenders and late-onset offenders. As Patterson and Yoerger discussed, poor and inept parenting practices lead to ineffective early childhood socialization, which allows for the development of oppositional/defiant behavior and early-onset offending. Furthermore, this ineffective socialization also causes these youth to be involved with deviant peers, which thereby magnifies their probability and intensity of offending. Patterson and Yoerger went on to suggest that early-onset offenders tend to be aggressive and defiant in their interactions with others and come to be rejected by conventional peers. Thus, these early-onset offenders tend to "find" one another and thereby form their own deviant peer groups, which places them at a high risk for chronic offending and continued offending over the life course.

In contrast, Patterson and Yoerger (1999) suggested that the late-onset offender group is not composed of individuals who suffer from poor and ineffective socialization; instead, the main cause of their offending is their interaction with deviant peers. Considering that the peer social context of adolescence is one of general support/acceptance for deviance, these late-onset offenders engage in delinquency during middle to late adolescence. However, because these youth did not enter into this developmental period suffering from ineffective childhood socialization they are able to confine their offending to this development period and go on to lead prosocial and productive adult lives. Several empirical studies have tested this theory and for the most part have supported the underlying assumptions of Patterson

and Yoerger's theory (see Simons, Johnson, Conger, & Elder, 1998; Simons, Wu, Conger, & Lorenz, 1994).

Loeber and his colleagues (Loeber, Farrington, Stouthamer-Loeber, Moffitt, & Caspi, 1998; Loeber, Wei, Stouthamer-Loeber, Huizinga, & Thornberry, 1999) have proposed a three-pathway model for describing the developmental progression of chronic offending. The first, the *overt pathway*, is believed to begin with minor acts of aggression, followed by physical fighting that ultimately escalates to violence. The second pathway, called the *covert pathway*, consists of a sequence of minor deviant behaviors followed by property damage and then escalates to more serious types of offending. The final pathway, the *authority-conflict pathway*, observed before age 12, consists of a sequence of stubborn behaviors, including defiance and authority avoidance (e.g., running away). Although according to Loeber et al.'s theoretical model individuals' developmental progression of delinquency can cross over the three pathways, the most frequent offenders are expected to be overrepresented among those in multiple pathways, particularly youth who exhibit overt and covert behavior problems.

With attention to the three pathways just described, it is important to mention that a key assumption of Loeber et al.'s (1998, 1999) theoretical model is that behavior takes place in an orderly, not random, fashion. Stated differently, an individual's pathway of offending is expected to progress through the lower-order steps before passing through the higher-order steps. Preliminary support for Loeber et al.'s pathway model was identified in the youngest sample of the Pittsburgh Youth Study and applied better to boys who persisted in delinquency compared with those who experimented in delinquency (Loeber et al., 1998). Furthermore, more recent replications of the pathway model have been provided in the three "Causes and Correlates Study" sites (Denver, Colorado; Pittsburgh, Pennsylvania; and Rochester, New York), although the findings were replicated only for Steps 2 and higher in the overt and covert pathways only (Loeber et al., 1999; although see Nagin & Tremblay, 1999).

One last DLC theory reviewed in this chapter is that of Sampson and Laub's (1993) age-graded theory of informal social control. This theory can best be described with attention to what Sampson and Laub characterized as a series of building blocks. The first building block focuses on the intervening role of informal family and school social bonds. The second building block focuses on the continuity of antisocial behavior that begins early in a child's development and extends throughout adulthood. They also recognized that particular life events and social ties in adulthood can alter an individual's behavioral trajectory, and this viewpoint is central to their third building block: the importance of adult social bonds. They proposed that social bonds developed in adulthood (employment, marriage) can explain involvement/lack of involvement in crime

regardless of any underlying individual criminal propensity. In addition, they emphasized that it is not only the mere exposure of individuals to these bonds that is critical but also the quality and intensity of these bonds. Drawing on the work of Elder (1985), Sampson and Laub also hypothesized that different adaptations to key life events can affect an individual's trajectory, and crucial turning points such as divorce or death of a loved one can redirect life trajectories.

In comparison, *cumulative continuity* (Moffitt, 1993) integrated with the concept of *state dependence* (for a review, see Nagin & Paternoster, 2000) refers to the idea that involvement in delinquency has an incremental effect on the interpersonal social bonds formed in adulthood (i.e., labor force attachment, marital cohesion). For instance, an arrest and subsequent incarceration in adolescence may lead the youth to drop out of school. This practice would logically affect his future job prospects and thus result in his failure to develop strong adulthood bonds to the labor force, which inevitably increases the likelihood of his involvement in crime (Tittle, 1988).

It is important to mention here that Sampson and Laub (1997) extended their age-graded theory of informal social control to incorporate a developmental conceptualization of labeling theory. Sampson and Laub suggested that involvement in delinquency has a "systematic attenuating effect on the social and institutional bonds linking adults to society (e.g., labor force attachment, marital cohesion)" (p. 144). Therefore, the relationship between delinquency and future criminal involvement is indirect in that delinquent participation leads to school failure, incarceration, and the development of weak bonds to the labor market, of which all of these factors are significantly associated with future criminal activity. Furthermore, for Sampson and Laub, this cycle occurs because severe sanctions label and stigmatize offenders, which thereby limits offenders' opportunity for involvement in a conventional lifestyle and participation in mechanisms of informal social control (e.g., legitimate employment). One early test of this theoretical model did in fact provide some preliminary support for Sampson and Laub's assumptions in that, compared with delinquents with a shorter incarceration history, boys who were incarcerated for a longer time had trouble securing stable jobs as they entered young adulthood (Sampson & Laub, 1997).

Although the DLC theories just reviewed are distinct from one another, they certainly share some common theoretical ground. Having said this, there is a clear divide. For example, Sampson and Laub's (1997) theory is dynamic general theory but allows for the possibility that key local life circumstances can alter an individual's criminal trajectory. In comparison, DLC theories such as Moffitt's (1993), Patterson and Yoerger (1999), and Loeber et al.'s (1998, 1999) assume not that causality is general but rather that there are different causal processes that explain different offender types. Furthermore, Moffitt's adolescent-limited offender

and Patterson and Yoerger's late-onset offender typologies are described as a state-dependent effect, whereas the causes of their life-course-persistent offender and early-onset offender counterpart typologies appear to emphasize persistent heterogeneity. Nevertheless, although this difference is important, most of the research has tended to favor taking the theoretical middle ground when studying crime (see Paternoster, Dean, Piquero, Mazerolle, & Brame, 1997), which suggests that explanations of persistent heterogeneity and state dependence are not necessarily incompatible or mutually inconsistent at all times.

Conclusion: Research Needs and Future Directions

On the basis of a review of the evidence, and with attention to the specific DLC theories covered in this chapter, it appears that there are many more questions than answers from this growing area of research and theorizing. This final section highlights several important research needs and anticipates several future directions for research on DLC criminology.

For instance, although DLC theories tend to express assumptions that have borrowed from research evidence across an array of disciplines, such as biology, public health, and the social sciences in general, there have not been many attempts to test these theories across the disciplines and/or involving cross-disciplinary collaborations among researchers in prior empirical tests. Second, recognizing that this is a relatively new area of criminological research, there have not been many attempts to date to incorporate multilevel models into tests of DLC theories. Studies such as these are likely to be highly beneficial to DLC research, because a number of these theories discuss risk and protective factors that are multilevel in nature (e.g., the importance of the school environment and residing in a disadvantaged neighborhood). Future research should attempt to collect and/or make use of macrolevel risk and protective factors when available and model these effects both independently and simultaneously alongside the individual-level risk and protective factors when empirically assessing DLC theories.

Another underdeveloped area of DLC research is an exploration of how many offender groups there may be. Although certain DLC theories suggest two offender groups (Moffitt, 1993; Patterson & Yoerger, 1999) and others discuss multiple pathways (Loeber et al., 1998, 1999), results from more than 80 studies using trajectory analysis have suggested between three to five offender groups (for a review, see Piquero, 2008). Some of these groups are consistent with notable DLC theories (e.g., adolescent-limited offenders and life-course-persistent offenders), whereas other groups that are not consistent with some DLC typologies, such as low-level chronic offenders and late-onset offenders (who do not begin their

offending until adulthood) have also emerged from this research. Future DLC studies should continue their efforts at replicating prior trajectory-analysis-based research in attempt to shed more light on the consistencies regarding the number of offender groups as well as incorporating risk and protective factors in their research to determine what covariates are significant for distinguishing trajectory group membership.

Last, DLC theories and related empirical research in the future should devote specific attention to race and gender. For the most part, the current DLC theories are relatively quiet on how race and gender may matter, or at the very least there have been only a handful of studies testing the generalizability of these theories across race and gender. Furthermore, a lot of the existing research in this area (similar to criminological research in general) relies either on self-report or official data. Although the limitations of both sources are well-known to criminologists, future DLC research should recognize this issue and attempt, when possible, to use some sort of a triangulation of methods to provide a more definitive conclusion on the progression of delinquency and criminal involvement over the life course. Thus, it is indeed an exciting time to be involved in DLC criminology, and as the subfield moves forward, those interested in this area of research may benefit from the suggestions given in this chapter as they become involved or continue their involvement with DLC criminological theory development and modification and/or empirical testing. This chapter closes by providing the reader with Farrington's (2003, pp. 229–230) excellent list of the key empirical and theoretical issues that need to be addressed by any DLC theory:

1. Why do people start offending?
2. How are onset sequences explained?
3. Why is there continuity in offending from adolescence to adulthood?
4. Why do people stop offending?
5. Why does prevalence peak in the teenage years?
6. Why does an early onset predict a long criminal career?
7. Why is there versatility in offending and antisocial behavior?
8. Why does co-offending decrease from adolescence to adulthood?
9. Why are there between-individual differences in offending?
10. What are the key risk factors for onset and desistance, and how can they be explained?
11. Why are there long-term (over life) and short-term (over time and place) within-individual differences in offending?
12. What are the main motives and reasons for offending?
13. What are the effects of life events on offending?

Key theoretical issues:

1. What is the key construct underlying offending?
2. What factors encourage offending?

3. What factors inhibit offending?
4. Is there a learning process?
5. Is there a decision-making process?
6. What is the structure of the theory?
7. What are operational definitions of theoretical constructs?
8. What does the theory explain?
9. What does the theory not explain?
10. What findings might challenge the theory? (Can the theory be tested?)
11. Crucial tests: How much does the theory make different predictions from another theory?

PSYCHOLOGICAL THEORIES OF CRIME

JOHN W. CLARK

Troy University

Why do individuals commit crimes? At the same time, why is crime present in our society? The criminal justice system is very concerned with these questions, and criminologists are attempting to answer them. In actuality, the question of why crime is committed is very difficult to answer. However, for centuries, people have been searching for answers (Jacoby, 2004). It is important to recognize that there are many different explanations as to why individuals commit crime (Conklin, 2007). One of the main explanations is based on psychological theories, which focus on the association among intelligence, personality, learning, and criminal behavior. Thus, in any discussion concerning crime causation, one must contemplate psychological theories.

When examining psychological theories of crime, one must be cognizant of the three major theories. The first is *psychodynamic theory*, which is centered on the notion that an individual's early childhood experience influences his or her likelihood for committing future crimes. The second is *behavioral theory*. Behavioral theorists have expanded the work of Gabriel Tarde through behavior modeling and social learning. The third is *cognitive theory*, the major premise of which suggests that an individual's perception and how it is manifested (Jacoby, 2004) affect his or her potential to commit crime. In other words, behavioral theory focuses on how an individual's perception of the world influences his or her behavior.

Also germane to psychological theories are personality and intelligence. Combined, these five theories or characteristics (i.e., psychodynamic, cognitive, behavioral,

personality, and intelligence) offer appealing insights into why an individual may commit a crime (Schmallegger, 2008). However, one should not assume this there is only one reason why a person commits crime. Researchers looking for a single explanation should be cautious, because there is no panacea for the problem of crime.

Early Research

Charles Goring (1870–1919) discovered a relationship between crime and flawed intelligence. Goring examined more than 3,000 convicts in England. It is important to note that Goring found no physical differences between noncriminals and criminals; however, he did find that criminals are more likely to be insane, to be unintelligent, and to exhibit poor social behavior. A second pioneer is Gabriel Tarde (1843–1904), who maintained that individuals learn from each other and ultimately imitate one another. Interestingly, Tarde thought that out of 100 individuals, only 1 was creative or inventive and the remainder were prone to imitation (Jacoby, 2004).

Psychodynamic Theory

Proponents of psychodynamic theory suggest that an individual's personality is controlled by unconscious mental processes that are grounded in early childhood. This theory

was originated by Sigmund Freud (1856–1939), the founder of psychoanalysis. Imperative to this theory are the three elements or structures that make up the human personality: (1) the *id*, (2), the *ego*, and (3) the *superego*. One can think of the *id* as the primitive part of a person's mental makeup that is present at birth. Freud (1933) believed the *id* represents the unconscious biological drives for food, sex, and other necessities over the life span. Most important is the idea that the *id* is concerned with instant pleasure or gratification while disregarding concern for others. This is known as the *pleasure principle*, and it is often paramount when discussing criminal behavior. All too often, one sees news stories and studies about criminal offenders who have no concern for anyone but themselves. Is it possible that these male and female offenders are driven by instant gratification? The second element of the human personality is the *ego*, which is thought to develop early in a person's life. For example, when children learn that their wishes cannot be gratified instantaneously, they often throw a tantrum. Freud (1933) suggested that the *ego* compensates for the demands of the *id* by guiding an individual's actions or behaviors to keep him or her within the boundaries of society. The *ego* is guided by the *reality principle*. The third element of personality, the *superego*, develops as a person incorporates the moral standards and values of the community; parents; and significant others, such as friends and clergy members. The focus of the *superego* is morality. The *superego* serves to pass judgment on the behavior and actions of individuals (Freud, 1933). The *ego* mediates between the *id*'s desire for instant gratification and the strict morality of the *superego*. One can assume that young adults as well as adults understand right from wrong. However, when a crime is committed, advocates of psychodynamic theory would suggest that an individual committed a crime because he or she has an underdeveloped *superego*.

In sum, psychodynamic theory suggests that criminal offenders are frustrated and aggravated. They are constantly drawn to past events that occurred in their early childhood. Because of a negligent, unhappy, or miserable childhood, which is most often characterized by a lack of love and/or nurturing, a criminal offender has a weak (or absent) *ego*. Most important, research suggests that having a weak *ego* is linked with poor or absence of social etiquette, immaturity, and dependence on others. Research further suggests that individuals with weak *egos* may be more likely to engage in drug abuse.

Mental Disorders and Crime

Within the psychodynamic theory of crime are *mood disorders*. Criminal offenders may have a number of mood disorders that are ultimately manifested as depression, rage, narcissism, and social isolation. One example of a disorder found in children is *conduct disorder*. Children

with conduct disorder have difficulty following rules and behaving in socially acceptable ways (Boccaccini, Murrie, Clark, & Comell, 2008). Conduct disorders are ultimately manifested as a group of behavioral and emotional problems in young adults. It is important to note that children diagnosed with conduct disorder are viewed by adults, other children, and agencies of the state as "trouble," "bad," "delinquent," or even "mentally ill." It is important to inquire as to why some children develop conduct disorder and others do not. There are many possible explanations; some of the most prominent include child abuse, brain damage, genetics, poor school performance, and a traumatic event.

Children with conduct disorder are more likely to exhibit aggressive behaviors toward others (Boccaccini et al., 2008), and they may be cruel to animals. Other manifestations include bullying; intimidation; fear; initiating fights; and using a weapon, such as a gun, a knife, a box cutter, rocks, a broken bottle, a golf club, or a baseball bat. Adolescents with conduct disorder could also force someone into unwanted sexual activity. Property damage may also be a concern; one may observe these children starting fires with the ultimate intent to destruct property or even kill someone. Other unacceptable behaviors associated with conduct disorder include lying and stealing, breaking into an individual's house or an unoccupied building or car, lying to obtain desirable goods, avoiding obligations, and taking possessions from individuals or stores. Last, children with conduct disorder are more likely to violate curfews despite their parents' desires. These children also are more likely to run away from home and to be late for or truant from school. There is no question that children who exhibit the above-mentioned behaviors must receive a medical and psychological examination. It is important to note that many children with conduct disorder could very well have another existing condition, such as anxiety, post-traumatic stress disorder, drug or alcohol abuse, or attention deficit disorder (Siegal, 2008). It is important to recognize that children with conduct disorder are likely to have continuing, long-lasting problems if they do not receive treatment at the earliest onset. Without treatment, these children will not be able to become accustomed to the demands of adulthood and will continue to have problems and issues with a variety of relationships and even with finding and maintaining a job or occupation. Treatment of children with conduct disorder is often considered complex and exigent. It is rarely brief, because establishing new attitudes and behavior patterns takes time. As mentioned previously, early treatment offers a child a greater probability for improvement and for ultimately living a productive and successful life. An important component for the medical doctor or psychological clinician to consider is convincing the child to develop a good attitude, learn to cooperate, trust others, and eliminate fear in their lives. Behavior therapy and psychotherapy may be necessary to help the child learn how to control and express anger. Moreover, special education classes

may be required for children with learning disabilities. In some cases, treatment may include prescribed medication, although medicine would ideally be reserved for children experiencing problems with depression, attention, or spontaneity/impulsivity. (For more information on conduct disorder, see <http://www.aacap.org>.)

A second example of a disorder found in children is *oppositional defiant disorder* (Siegal, 2008). This is most often diagnosed in childhood. Manifestations or characterizations of oppositional defiant disorder include defiance; uncooperativeness; irritability; a very negative attitude; a tendency to lose one's temper; and exhibiting deliberately annoying behaviors toward peers, parents, teachers, and other authority figures, such as police officers (Siegal, 2008). There is no known cause of oppositional defiant disorder; however, there are two primary theories that attempt to explain its development. One theory suggests that problems begin in children as early as the toddler years. It is important to note that adolescents and small children who develop oppositional defiant disorder may have experienced a difficult time developing independent or autonomous skills and learning to separate from their primary caretaker or attachment figure. In essence, the bad attitudes that are characteristic of oppositional defiant disorder are viewed as a continuation of developmental issues that were not resolved during the early toddler years.

The second theory to explain oppositional defiant disorder focuses on learning. This theory suggests the negative characteristics of oppositional defiant disorder are learned attitudes that demonstrate the effects of negative reinforcement used by parents or persons in authority (Siegal, 2009). It is important to recognize that the majority of symptoms observed in adolescents and children with oppositional defiant disorder also occur, at times, in children without this disorder. Relevant examples include a child who is hungry, tired, troubled, or disobeys/argues with his or her parent. It is important to note that adolescents and children with oppositional defiant disorder often exhibit symptoms that hinder the learning process, lead to poor adjustment in school, and most likely hurt the child's relationships with others. Some of the symptoms of oppositional defiant disorder include frequent temper tantrums, excessive arguments with adults, refusal to comply with adult requests, questioning rules, refusing to follow rules, engaging in behavior intended to annoy or upset others, blaming others for one's misbehaviors or mistakes, being easily annoyed by others, frequently having an angry attitude, speaking harshly or unkindly, and deliberately behaving in ways that seek revenge.

In regard to diagnosis, it is often teachers and parents who identify the child or adolescent with oppositional defiant disorder. However, children must be taken to a qualified medical doctor and/or mental health professional who will make an official diagnosis. Doctors will inquire into the history of the child's behavior, which includes the perspective of all interested parties (i.e., parents and teachers) and

will verify the results of any previous clinical observations of the child's behavior. Psychological testing also may assist in assigning a diagnosis. As always, early detection and treatment are desirable. Actually, early treatment can often prevent future problems.

Oppositional defiant disorder may exist alongside other mental health problems, including mood and anxiety disorders, conduct disorder, and attention deficit hyperactivity disorder. Treatment for children and adolescents with oppositional defiant disorder will be determined by a physician who considers the child's age, overall health, and medical history. The physician also considers the extent or totality of a child's symptoms, the child's tolerance for certain medications or therapies, expectations for the course of the condition, and the opinion or preference of the caretaker or parent. Most important, treatment could include psychotherapy that teaches problem-solving skills, communication skills, impulse control, and anger management skills. Treatment may also be in the form of family therapy. Here, the approach is focused on making changes within the family system with the desired goal of improved family interaction and communication skills. Peer group therapy, which is focused on developing social skills and interpersonal skills, also is an option. The last and least desirable treatment option is medication. (For more information on oppositional defiant disorder, see <http://www.aacap.org>.)

Mental Illness and Crime

The most serious forms of personality disturbance will result in mental disorders. The most serious mental disturbances are referred to as *psychoses* (Siegal, 2008). Examples of mental health disorders include bipolar disorder and schizophrenia. Bipolar disorder is marked by extreme highs and lows; the person alternates between excited, assertive, and loud behavior and lethargic, listless, and melancholic behavior. A second mental health disturbance is schizophrenia. Schizophrenic individuals often exhibit illogical and incoherent thought processes, and they often lack insight into their behavior and do not understand reality. A person with paranoid schizophrenia also experiences complex behavior delusions that involve wrongdoing or persecution (Jacoby, 2004). Individuals with paranoid schizophrenia often believe everyone is out to get them. It is important to note that research shows that female offenders appear to have a higher probability of serious mental health symptoms than male offenders. These include symptoms of schizophrenia, paranoia, and obsessive behaviors. At the same time, studies of males accused of murder have found that three quarters could be classified as having some form of mental illness. Another interesting fact is that individuals who have been diagnosed with a mental illness are more likely to be arrested, and they appear in court at a disproportionate rate. Last, research suggests that delinquent children have a higher

rate of clinical mental disorders compared with adolescents in the general population (Siegal, 2008).

Behavioral Theory

The second major psychological theory is *behaviorism*. This theory maintains that human behavior is developed through learning experiences. The hallmark of behavioral theory is the notion that people alter or change their behavior according to the reactions this behavior elicits in other people (Bandura, 1978). In an ideal situation, behavior is supported by rewards and extinguished by negative reactions or punishments. Behaviorists view crimes as learned responses to life's situations. *Social learning theory*, which is a branch of behavior theory, is the most relevant to criminology. The most prominent social learning theorist is Albert Bandura (1978). Bandura maintains that individuals are not born with an innate ability to act violently. He suggested that, in contrast, violence and aggression are learned through a process of behavior modeling (Bandura, 1977). In other words, children learn violence through the observation of others. Aggressive acts are modeled after three primary sources: (1) family interaction, (2) environmental experiences, and (3) the mass media. Research on family interaction demonstrates that children who are aggressive are more likely to have been brought up by parents or caretakers who are aggressive (Jacoby, 2004).

The second source of behavioral problems, environmental experiences, suggests that individuals who reside in areas that are crime prone are more likely to display aggressive behavior than those who reside in low-crime areas (Shelden, 2006). One could argue that high-crime areas are without norms, rules, and customs (Bohm, 2001). Furthermore, there is an absence of conventional behavior. Manifestations of unconventional behavior include the inability to gain employment; drug or alcohol abuse; and failure to obey the local, state, and federal laws. Most important, individuals who adhere to conventional behavior are invested in society and committed to a goal or belief system. They are involved in schools or extracurricular activities, such as football, baseball, or Girl Scouts, and often they have an attachment to family (Kraska, 2004).

The third source of behavioral problems are the mass media. It is difficult to discern the ultimate role of the media in regard to crime. Scholars have suggested that films, video games, and television shows that depict violence are harmful to children. Ultimately, social learning theories beckon us to accept the fact that the mass media are responsible for a great deal of the violence in our society. They hypothesize that children who play violent video games and later inflict physical or psychological damage to someone at school did so because of the influence of the video game. Important to note that in the above-mentioned media outlets (e.g., video games), violence is often acceptable and even celebrated. Moreover, there are no consequences for the actions of the major players. Professional athletes provide an interesting

example of misbehavior without significant consequences. Over the last 50 years, there have been many documented cases of professional athletes who engaged in inappropriate behavior on and off the field. These cases have important implications for the children who observe this behavior. Thus, when a 10-year-old amateur athlete imitates behavior that he has learned by observing professional sports figures, whom does society blame or punish? Substantiating the relationship between the media and violence is the fact that many studies suggest that media violence enables or allows aggressive children or adolescents to justify or rationalize their behavior. Furthermore, consistent media violence desensitizes children and adolescents. A person could argue that viewing 10,000 homicides on television over a 10-year period prevents (i.e., desensitizes) an individual from adjusting to the appropriate psychological response. Thus, when the local news reports about a homicide, does the child or adolescent respond with sorrow or indifference (Jacoby, 2004)? When searching for stimuli that foster violent acts, social learning theorists suggest that an individual is likely to inflict harm when he or she is subject to a violent assault, verbal heckling or insults, disparagement, and the inability to achieve his or her goals and aspirations (Siegal, 2009).

Cognitive Theory

A third major psychological theory is *cognitive theory*. In recent years, significant gains have been made in explaining criminal behavior within the cognitive theory framework. Here, psychologists focus on the mental processes of individuals. More important, cognitive theorists attempt to understand how criminal offenders perceive and mentally represent the world around them (Knepper, 2001). Germane to cognitive theory is how individuals solve problems. Two prominent pioneering 19th-century psychologists are Wilhelm Wundt and William James. Two subdisciplines of cognitive theory are worthy of discussion. The first subdiscipline is the *moral development* branch, the focus of which is understanding how people morally represent and reason about the world. The second subdiscipline is *information processing*. Here, researchers focus on the way people acquire, retain, and retrieve information (Siegal, 2009). Ultimately, scholars are concerned with the process of those three stages (i.e., acquisition, retention, and retrieval). One theory within the cognitive framework focuses on moral and intellectual development. Jean Piaget (1896–1980) hypothesized that the individual reasoning process is developed in an orderly fashion. Thus, from birth onward an individual will continue to develop. Another pioneer of cognitive theory is Lawrence Kohlberg (1927–1987), who applied the concept of moral development to criminological theory. Kohlberg (1984) believed that individuals pass through stages of moral development. Most important to his theory is the notion that there are levels, stages, and social orientation. The three levels are Level I, preconventional; Level II, conventional; and Level III,

postconventional. With respect to the different stages, Stages 1 and 2 fall under Level I. Stages 3 and 4 fall under Level II, and Stages 5 and 6 fall under Level III.

Stage 1 is concerned about obedience and punishment. This level is most often found at the grade levels of kindergarten through fifth grade. During this stage, individuals conduct themselves in a manner that is consistent with socially acceptable norms (Kohlberg, 1984). This conforming behavior is attributed to authority figures such as parents, teachers, or the school principal. Ultimately, this obedience is compelled by the threat or application of punishment. Stage 2 is characterized by individualism, instrumentalism, and exchange. Ultimately, the characterization suggests that individuals seek to fulfill their own interests and recognize that others should do the same. This stage maintains that the right behavior means acting in one's own best interests (Kohlberg, 1984).

The conventional level of moral reasoning is often found in young adults or adults. It is believed that individuals who reason in a conventional way are more likely to judge the morality of actions by comparing those actions to societal viewpoints and expectations (Kohlberg, 1984). The third and fourth stages fall under this level of development. In Stage 3, the individual recognizes that he or she is now a member of society. Coinciding with this is the understanding of the roles that one plays. An important concept within this stage is the idea that individuals are interested in whether or not other people approve or disapprove of them (Kohlberg, 1984). For example, if you are an attorney, what role does society expect you to play? Tangentially, what role does the clergy hold in society? It is important to note that perception is germane to this stage as well. Ultimately, the literature suggests this is where a "good" boy and girl attempts to ascertain his or her standing or role within society. With respect to stage four, the premise is based on law and order. In this stage, individuals recognize the importance of laws, rules, and customs. This is important because in order to properly function in society, one must obey and recognize the social pillars of society. Ultimately, individuals must recognize the significance of right and wrong. Obviously, a society without laws and punishments leads to chaos. In contrast, if an individual who breaks the law is punished, others would recognize that and exhibit obedience. Kohlberg (1984) suggested that the majority of individuals in our society remain at this stage, in which morality is driven by outside forces.

Stages 5 and 6 exist at the postconventional level. Stage 5 is referred to as the *social contract*. Here, individuals are concerned with the moral worth of societal rules and values, but only insofar as they are related to or consistent with the basic values of liberty, the welfare of humanity, and human rights. Fundamental terms associated with this stage are *majority decision* and *compromise*. Stage 6 is often termed *principled conscience*. This stage is characterized by universal principles of justice and respect for human autonomy. Most important to criminal justice and criminology is the notion that laws are valid only if they are based

on or grounded in justice. It is important to recognize that justice is subjective. Thus, Kohlberg argued that the quest for justice would ultimately call for disobeying unjust laws. He suggested that individuals could progress through the six stages in a chronological fashion. Important for criminology is that Kohlberg suggested that criminals are significantly lower in their moral judgment development.

The next subdiscipline is the *information-processing* branch. This area is predicated on the notion that people use information to understand their environment. When an individual makes a decision, he or she engages in a sequence of cognitive thought processes. To illustrate, individuals experience an event and encode or store the relevant information so it can be retrieved and interpreted at a later date (Conklin, 2007). Second, these individuals search for the appropriate response, and then they determine the appropriate action. Last, they must act on their decision. There are some vital findings regarding this process. First, individuals who use information properly are more likely to avoid delinquent or criminal behavior (Shelden, 2006). Second, those who are conditioned to make reasoned judgments when faced with emotional events are more likely to avoid antisocial behavioral decisions (Siegal, 2008). Interestingly, an explanation for flawed reasoning is that the individual may be relying on a faulty cognitive process; specifically, he or she may be following a mental script that was learned in childhood (Jacoby, 2004). A second reason that may account for flawed reasoning is prolonged exposure to violence. A third possibility of faulty reasoning is oversensitivity or rejection by parents or peers. Contemplating the consequences of long-lasting rejection or dismissal is likely to produce damage to an individual's self-esteem. Research has demonstrated that individuals who use violence as a coping mechanism are substantially more likely to exhibit other problems, such as alcohol and drug dependency (Piquero & Mazarolle, 2001).

Personality and Crime

Personality can be defined as something that makes us what we are and also that which makes us different from others (Clark, Boccaccini, Caillouet, & Chaplin, 2007). Ideally, personality is stable over time. Examinations of the relationship between personality and crime have often yielded inconsistent results. One of the most well-known theories of personality used to examine this relationship is the Big Five model of personality. This model provides a vigorous structure into which most personality characteristics can be categorized. This model suggests that five domains account for individual differences in personality: (1) Neuroticism, (2) Extraversion, (3) Openness, (4) Agreeableness, and (5) Conscientiousness (Clark et al., 2007). Neuroticism involves emotional stability. Individuals who score high on this domain often demonstrate anger and sadness and have irrational ideas, uncontrollable impulses, and anxiety. In contrast, persons who score low on Neuroticism are often described by others as even tempered, calm, and relaxed.

The second domain, Extraversion, is characterized by sociability, excitement, and stimulation. Individuals who score high on Extraversion (extraverts) are often very active, talkative, and assertive. They also are more optimistic toward the future. In contrast, introverts are often characterized by being reserved, independent, and shy (Clark et al., 2007).

The third domain is Openness, referring to individuals who have an active imagination, find pleasure in beauty, are attentive to their inner feelings, have a preference for variety, and are intellectually curious. Individuals who score high on Openness are willing to entertain unique or novel ideas, maintain unconventional values, and experience positive and negative emotions more so than individuals who are closed-minded. In contrast, persons who score low in Openness often prefer the familiar, behave in conventional manners, and have a conservative viewpoint (Clark et al., 2007).

The fourth domain is Agreeableness. This domain is related to interpersonal tendencies. Individuals who score high on this domain are considered warm, altruistic, soft-hearted, forgiving, sympathetic, and trusting. In contrast, those who are not agreeable are described as hard-hearted, intolerant, impatient, and argumentative.

Conscientiousness, the fifth domain, focuses on a person's ability to control impulses and exercise self-control. Individuals who score high on Conscientiousness are described as organized, thorough, efficient, determined, and strong willed. In addition, those who are conscientious are more likely to achieve high academic and occupational desires. In contrast, people who score low on this domain are thought to be careless, lazy, and more likely assign fault to others than to accept blame themselves (Clark et al., 2007).

One personality study discovered that the personality traits of hostility, impulsivity, and narcissism are correlated with delinquent and criminal behavior. Furthermore, research conducted by Sheldon and Eleanor Glueck during the 1930s and 1940s identified a number of personality traits that were characteristic of antisocial youth (Schmallegger, 2008). Another important figure who examined the criminal personality is Hans Eysenck (1916–1997). Eysenck identified two antisocial personality traits: (1) extraversion and (2) neuroticism. Eysenck suggested that individuals who score at the ends of either domain of extraversion and neuroticism are more likely to be self-destructive and criminal (Eysenck & Eysenck, 1985). Moreover, neuroticism is associated with self-destructive behavior (e.g., abusing drugs and alcohol and committing crimes).

Psychopathic Personality

Antisocial personality, psychopathy, or sociopath are terms used interchangeably (Siegal, 2009). Sociopaths are often a product of a destructive home environment. Psychopaths are a product of a defect or aberration within themselves. The antisocial personality is characterized by low levels of guilt, superficial charm, above-average intelligence, persistent violations of the rights of others, an incapacity to form

enduring relationships, impulsivity, risk taking, egocentricity, manipulateness, forcefulness and cold-heartedness, and shallow emotions (Jacoby, 2004). The origin may include traumatic socialization, neurological disorder, and brain abnormality (Siegal, 2008). Interestingly, if an individual suffers from low levels of arousal as measured by a neurological examination, he or she may engage in thrill seeking or high-risk behaviors such as crime to offset their low arousal level. Other dynamics that may contribute to the psychopathic personality is a parent with pathologic tendencies, childhood traumatic events, or inconsistent discipline. It is important to note that many chronic offenders are sociopaths. Thus, if personality traits can predict crime and violence, then one could assume that the root cause of crime is found in the forces that influence human development at an early stage of life (Siegal, 2008).

Intelligence and Crime

Criminologists have suggested for centuries that there exists a link between intelligence and crime (Dabney, 2004). Some common beliefs are that criminals and delinquents possess low intelligence and that this low intelligence causes criminality. As criminological research has advanced, scholars have continued to suggest that the Holy Grail is causality. The ability to predict criminals from noncriminals is the ultimate goal. The ideology or concept of IQ and crime has crystallized into the nature-versus-nurture debate (Jacoby, 2004).

The nature-versus-nurture debate is a psychological argument that is related to whether the environment or heredity impacts the psychological development of individuals (Messner & Rosenfield, 2007). Science recognizes that we share our parents' DNA. To illustrate, some people have short fingers like their mother and brown eyes like their father. However, the question remains: Where do individuals get their love of sports, literature, and humor? The nature-versus-nurture debate addresses this issue. With respect to the nature side, research on the prison population has consistently shown that inmates typically score low on IQ tests (Schmallegger, 2008). In the early decades of the 20th century, researchers administered IQ tests to delinquent male children. The results indicated that close to 40% had below-average intelligence (Siegal, 2008). On the basis of these data and other studies, some scholars argue that the role of nature is prevalent. However, can researchers assume a priori that heredity determines IQ, which in turn influences an individual's criminal behavior? One criticism of this perspective is the failure to account for free will. Many individuals in our society believe in the ability to make choices. Last, there are many individuals who have a low IQ but refrain from committing crime.

With respect to nurture theory, advocates ground themselves on the premise that intelligence is not inherited. There is some recognition of the role of heredity; however, emphasis is placed on the role of society (i.e., environment).

To demonstrate, parents are a major influence on their children's behavior. At an early age, parents read books; play music; and engage their children in art, museum, and sporting events. Some parents spend no quality time with their children, and these children are believed to perform poorly on intelligence test. Other groups important in a child's nurturing are friends, relatives, and teachers. Ultimately, the child who has no friends or relatives and drops out of school is destined for difficult times. Research has demonstrated that the more education a person has, the higher his or her IQ.

The nature-versus-nurture debate will continue. The debate has peaks and valleys. For years, the debate subsides, and this is followed by years of scrutiny and a great deal of attention. One of two major studies that highlighted this debate was conducted by Travis Hirschi and Michael Hindelang (1977). These scholars suggested that low IQ increases the likelihood of criminal behavior through its effect on school performance. This argument seems somewhat elementary. Their argument is that a child with a low IQ will perform poorly in school. In turn, this school failure is followed by dropping out. Given the poor school performance, a child is left with very few options (Hirschi & Hindelang, 1977). This ultimately leads to delinquency and adult criminality. Support of this position has been widespread. Furthermore, it is important to note that U.S. prisons and jails are highly populated with inmates who only have an average of eighth-grade education. At the same time, these same inmates at the time of their offense were unemployed.

The second nature-versus-nature study that warrants attention was conducted by Richard Herrnstein and Charles Murray (1994). In their book *The Bell Curve*, these scholars suggested individuals with a lower IQ are more likely to commit crime, get caught, and be sent to prison. Importantly, these authors transport the IQ and crime link to another level. Specifically, they suggested that prisons and jails are highly populated with inmates with low IQs; however, what about those criminals whose actions go undetected? Through self-reported data, the researchers discovered that these individuals have a lower IQ than the general public. Thus, research concludes those criminal offenders who have been caught and those who have not have an IQ lower than the general population (Herrnstein & Murray, 1994).

Conclusion

The relationship between psychology and criminal behavior is significant. For centuries, scholars have been attempting to explain why someone commits a crime. This chapter examined the role of psychodynamic theory as developed by Sigmund Freud. Included here are the roles of the id, ego, and superego in criminal behavior. This was followed by a discussion of mental disorders and crime. Under examination here were conduct disorder and oppositional defiant disorder. Through both disorders, we learned that children possess many characteristics associated with delinquency and adult criminality, ultimately concluding that treatment is a necessity and early intervention is paramount.

Discussed next was the role of mental illness and crime. Bipolar disorder and schizophrenia are two of the most serious disorders. Research suggests that there is a correlation between individuals with bipolar disorder and schizophrenia and delinquency and/or criminal behavior. The second major psychological theory is behaviorism. As previously mentioned, behavioral theory suggests human behavior is fostered through learning experiences. At the forefront of this theory is the premise that individuals change their behavior according to reactions from others. In the real world, there exists the assumption that behavior is reinforced via rewards and eliminated by a negative reaction or punishment. Social learning theory, which is a branch of behavior theory, is the most relevant to criminology. Moreover, the most prominent social learning theorist is Albert Bandura.

The third psychological theory examined is cognition. Here, an importance of mental processes of individuals is examined. A discussion followed on how individuals perceive and mentally represent the world. Furthermore, how do individuals solve problems? Two important subdisciplines examined were Kohlberg's moral development theory and information-processing theory. Ultimately, we can conclude that criminal offenders are poor at processing information and evaluating the world around them. The next major topics discussed were personality and intelligence. Concerning personality, we learned that personality can be measured via the domains of Neuroticism, Extraversion, Openness, Agreeableness, and Conscientiousness. We learned that Extraversion and Neuroticism are related to criminal behavior. Last, the intelligence debate has existed for centuries, and data demonstrate that individuals with a low IQ are more likely to engage in criminal behavior. Important to the discussion of intelligence and IQ is school performance. Research studies that have examined future delinquency and adult criminality have consistently demonstrated the link between the two. In reality, it is not difficult to understand why a person who fails or drops out of school is limited in his or her career or future options. Occupations that have desirable salaries often require a high school degree as well as a bachelor's or master's degree. In sum, when citizens and scholars attempt to understand why people commit a crime, recognition must be given to psychological theories. Not doing so would be a serious error in judgment.

ROUTINE ACTIVITIES

MARIE SKUBAK TILLYER

University of Texas at San Antonio

JOHN E. ECK

University of Cincinnati

R*outine activities theory* is a theory of crime events. This differs from a majority of criminological theories, which focus on explaining why some people commit crimes—that is, the motivation to commit crime—rather than how criminal events are produced. Although at first glance this distinction may appear inconsequential, it has important implications for the research and prevention of crime. Routine activities theory suggests that the organization of routine activities in society create opportunities for crime. In other words, the daily routine activities of people—including where they work, the routes they travel to and from school, the groups with whom they socialize, the shops they frequent, and so forth—strongly influence when, where, and to whom crime occurs. These routines can make crime easy and low risk, or difficult and risky. Because opportunities vary over time, space, and among people, so too does the likelihood of crime. Therefore, research that stems from routine activities theory generally examines various opportunity structures that facilitate crime; prevention strategies that are informed by routine activities theory attempt to alter these opportunity structures to prevent criminal events.

Routine activities theory was initially used to explain changes in crime trends over time. It has been increasingly used much more broadly to understand and prevent crime problems. Researchers have used various methods to test hypotheses derived from the theory. Since its inception, the theory has become closely aligned with a set of theories and perspectives known as *environmental criminology*, which

focuses on the importance of opportunity in determining the distribution of crime across time and space. Environmental criminology, and routine activities theory in particular, has very practical implications for prevention; therefore, practitioners have applied routine activities theory to inform police practices and prevention strategies. This chapter contains a review of the evolution of routine activities theory; a summary of research informed by the theory; complementary perspectives and current applications; and future directions for theory, research, and prevention.

Theory

In 1979, Cohen and Felson questioned why urban crime rates increased during the 1960s, when the factors commonly thought to cause violent crime, such as poor economic conditions, had generally improved during this time. Cohen and Felson (1979) suggested that a *crime* should be thought of as an event that occurs at a specific location and time and involves specific people and/or objects. They argued that crime events required three minimal elements to converge in time and space: (1) an offender who was prepared to commit the offense; (2) a suitable target, such as a human victim to be assaulted or a piece of property to be stolen; and (3) the absence of a guardian capable of preventing the crime. The lack of any of these three elements, they argued, would be sufficient to prevent a crime event from occurring. Drawing from human ecological theories,

Cohen and Felson suggested that structural changes in societal routine activity patterns can influence crime rates by affecting the likelihood of the convergence in time and space of these three necessary elements. As the routine activities of people change, the likelihood of targets converging in time and space with motivated offenders without guardians also changes. In other words, opportunities for crime—and, in turn, crime patterns—are a function of the routine activity patterns in society.

Cohen and Felson (1979) argued that crime rates increased after World War II because the routine activities of society had begun to shift away from the home, thus increasing the likelihood that motivated offenders would converge in time and space with suitable targets in the absence of capable guardianship. Routine activities that take place at or near the home tend to be associated with more guardianship—for both the individual and his or her property—and a lower risk of encountering potential offenders. When people perform routine activities away from the home, they are more likely to encounter potential offenders in the absence of guardians. Furthermore, their belongings in their home are left unguarded, thus creating more opportunities for crime to take place.

One of the greatest contributions of routine activities theory is the idea that criminal opportunities are not spread evenly throughout society; neither are they infinite. Instead, there is some limit on the number of available targets viewed as attractive/suitable by the offender. Cohen and Felson (1979) suggested that suitability is a function of at least four qualities of the target: Value, Inertia, Visibility, and Access, or VIVA. All else being equal, those persons or products that are repeatedly targeted will have the following qualities: perceived value by the offender, either material or symbolic; size and weight that makes the illegal treatment possible; physically visible to potential offenders; and accessible to offenders. Cohen and Felson argued that two additional societal trends—the increase in sales of consumer goods and the design of small durable products—were affecting the crime by means of the supply of suitable targets. These trends in society increased the supply of suitable targets available and, in turn, the likelihood of crime. As the supply of small durable goods continued to rise, the level of suitable targets also rose, thus increasing the number of available criminal opportunities.

Since its inception, routine activities theory has been developed to further specify the necessary elements for a criminal event and those that have the potential to prevent it. The people who prevent crime have been subdivided according to whom or what they are supervising—offender, target, or place—and are now collectively referred to as *controllers*. *Handlers* are people who exert informal social control over potential offenders to prevent them from committing crimes (Felson, 1986). Examples of handlers include parents who chaperone their teenager's social gatherings, a probation officer who supervises probationers, and a school resource officer who keeps an eye on school bullies. Handlers have some sort of personal connection with the potential offenders.

Their principal interest is in keeping the potential offender out of trouble. *Guardians* protect suitable targets from offenders (Cohen & Felson, 1979). Examples of guardians include the owner of a car who locks his vehicle, a child care provider who keeps close watch over the children in public, and a coworker who walks another to his car in the parking garage. The principal interest of guardians is the protection of their potential targets. Finally, *managers* supervise and monitor specific places (Eck, 1994). Place managers might include the owner of a shop who installs surveillance cameras, an apartment landlord who updates the locks on the doors, and park rangers who enforce littering codes. The principal interest of managers is the functioning of places. Eck (2003) depicted this more comprehensive version of routine activities theory as a crime triangle (see Figure 32.1).

The inner triangle represents the necessary elements for a crime to occur: A motivated offender and suitable target must be at the same place at the same time. The outer triangle represents the potential controllers—guardians, handlers, and managers—who must be absent or ineffective for a crime to occur; the presence of one effective controller can prevent the criminal event.

Controllers have been described in greater detail. Felson (1995) indicated who is most likely to successfully control crime as a guardian, handler, or manager. He asserted that individuals' tendency to discourage crime—by supervising targets, offenders, or places—varies with degree of responsibility. He described four varying degrees of responsibility:

1. *Personal*, such as owners, family, and friends
2. *Assigned*, such as employees with a specific assigned responsibility
3. *Diffuse*, such as employees with a general assigned responsibility
4. *General*, such as strangers and other citizens

Controllers who are more closely associated with potential offenders, targets, or places, are more likely to

Figure 32.1 The Crime Triangle

successfully take control and prevent crime. As responsibility moves from personal to general, the likelihood that crime will be prevented diminishes. For example, a shop owner will be much more likely to take control and prevent shoplifting in her store compared with a stranger who infrequently comes to the store. Residents will be more likely to prevent crime on their own street block, rather than on the blocks they travel to and from work.

The characteristics of a suitable target have been expanded and applied to products that are frequently targeted for theft. Clarke (1999) extended Cohen and Felson's (1979) work on target suitability to explain the phenomenon of "hot products." Clarke suggested that relatively few hot products account for a large proportion of all thefts. He argues there are six key attributes of hot products that increase the likelihood that they will be targeted by thieves. Specifically, crime is concentrated on products that are CRAVED, that is, Concealable, Removable, Available, Valuable, Enjoyable, and Disposable (Clarke, 1999).

To summarize, routine activities theory is a theory of crime events. Routine activities theory differs from other criminological theories in a fundamental way. Before the advent of routine activities theory, nearly all criminological theory had focused solely on factors that motivate offenders to behave criminally, such as biological, sociological, and economic conditions that might drive individuals to commit crimes. Conversely, routine activities theory focuses on a range of factors that intersect in time and space to produce criminal opportunities and, in turn, criminal events. Although standard criminological theories do not explain how crimes happen to occur at some places (but not others), at some times (but not others), and to some targets (but not others), routine activities theory does not explain why some people commit crimes and others do not. It is important to note that routine activities theory suggests that crime can increase and decline without any change in the number of criminals. Instead, there might be an increase in the availability of suitable targets, a decline in the availability or effectiveness of controllers, or a shift in the routine activities of society that increase the likelihood that these elements will converge in time and space. This notion that the offender is but one contributor to the crime event has both theoretical and practical implications. First, it insinuates that theories that focus only on offender factors are not sufficient to explain crime patterns and trends, only the supply of motivated offenders. Second, it suggests a much broader range of prevention possibilities. Whereas other criminological theories suggest changes to the social, economic, and political institutions of society to alter the factors that motivate people to commit crimes, routine activities theory indicates that shifts in the availability of suitable targets; the characteristics of places; and the presence of capable guardians, place managers, or handlers can produce immediate reductions in crime. Furthermore, changes in the routine activity patterns of society that affect the likelihood that these elements will converge in space and time can also prevent crime events

without directly affecting the supply of motivated offenders. Given these policy implications, researchers have derived various testable hypotheses from routine activities theory to explore its validity.

Methods

Routine activities theory has guided research designed to understand a range of phenomena, including crime trends over time, distributions of crime across space, and individual differences in victimization. In addition, researchers have considered how opportunities for crime might exist at multiple levels. For example, the characteristics of one's neighborhood and the features of the home might influence the likelihood of burglary victimization. Researchers have used various research methods to meet these different needs. The selection of research reviewed in the following paragraphs illustrates the different methods researchers have used to test hypotheses developed from routine activities theory.

Using Routine Activity to Predict Crime Trends

Routine activities theory was first used to understand changes in crime trends over time. To do this, researchers examine how crime rates fluctuate over time with changes in macrolevel routine activity trends to determine whether changes in routine activities are associated with changes in crime trends. If they are, this indicates support for the theory. In their initial presentation of the theory, Cohen and Felson (1979) pointed to a shift in the structural routine activities of society to explain why urban crime rates increased during the 1960s, when the factors thought to cause violent crime, such as economic conditions, had generally improved during this time period. They argued that the dispersion in activities away from the family and household caused an increase in target suitability and a decrease in guardianship. In other words, people were leaving their households unoccupied and unguarded more frequently, as well as exposing themselves as targets to potential motivated offenders. To test this hypothesis, Cohen and Felson developed a *household activity ratio* to measure the extent to which households were left unattended.¹ They predicted that changes in the dispersion of activities away from the family and household explained crime rates over time, arguing that nonhousehold activities increase the probability that motivated offenders will converge in time and space in the absence of capable guardians. Using a time series analysis, they found that the household activity ratio was significantly related to burglary, forcible rape, aggravated assault, robbery, and homicide rates from 1947 to 1974 (Cohen & Felson, 1979). Consistent with Cohen and Felson's initial study, subsequent macrolevel studies have demonstrated that variations in society's structural organization of routine activities are related to variations in crime trends over time (e.g., Felson & Cohen, 1980). In other

words, research has generally shown that routine activities that take people away from their home tend to be associated with increases in crime rates.

Using Routine Activities to Predict the Distribution of Crime Across Space

Routine activities theory has also been used to explain distributions of crime across space. Unlike the research just reviewed, which examined how crime rates changed in the same place over time (i.e., the United States from year to year), this type of research examines how crime rates differ across various places at the same time (i.e., different cities in the United States during a given year). Researchers have used routine activities theory to develop testable hypotheses about why some areas have higher crime rates than others. To do this, they examine whether the routine activities of people living in places with higher levels of crime differ from the routine activities of people living in places with lower levels of crime. For example, Messner and Blau (1987) hypothesized that routine leisure activities that take place in the household will result in lower crime rates, whereas those that take people away from their households will result in higher crime rates. To test these hypotheses, they used data from the 124 largest Standard Metropolitan Statistical Areas in the United States during the time period around 1980. Specifically, they hypothesized that higher levels of aggregate television viewing would be associated with lower city crime rates, because routine leisure activities that take place in the household provide potential targets with a greater level of guardianship. Conversely, they hypothesized that a greater supply of sports and entertainment establishments will be associated with higher city crime rates, because leisure activities that remove people from their homes leave suitable targets unguarded. In general, their analyses support these hypotheses. Higher levels of television viewing were associated with lower rates of forcible rape, robbery, aggravated assault, burglary, larceny, and auto theft. Conversely, a greater supply of sports and entertainment establishments was associated with higher rates of murder and nonnegligent manslaughter, forcible rape, robbery, aggravated assault, burglary, and larceny.

Using Routine Activities to Predict Differences in Victimization

Routine activities theory has also been used to explain differences in victimization across individuals. Although Cohen and Felson (1979) initially used the theory to explain national-level crime trends, the mechanisms described by the theory are actually microlevel in nature: A victim comes into contact with an offender in the absence of any capable controllers. This has led many researchers to use individual-level victimization data to understand differences in victimization risk given the routine activities of the potential victim. Specifically, researchers compare the routine activities of victims to those of nonvictims to

understand the effect of lifestyle and routine activities on the likelihood of victimization. Victimization survey data have become increasingly available in recent decades, making such methodology more common. Therefore, researchers have examined how the routine activities of individuals affect their likelihood of various forms of victimization, including property crime (e.g., Mustaine & Tewksbury, 1998), violent crime (e.g., Sampson, 1987), and stalking (e.g., Fisher, Cullen, & Turner, 2002)

Miethe, Stafford, and Long (1987) argued that the routine activities of individuals differentially place some people and/or their property in the proximity of motivated offenders, thus leaving them vulnerable to victimization. Using victimization data from the 1975 National Crime Survey, Miethe et al. explored whether individuals' major daily activities and frequency of nighttime activities affected their likelihood of property and violent victimization. Their analyses indicated that individuals who performed their major daily activities outside of the home had relatively higher risks of property victimization compared with those whose daily activities kept them at home. The location of major daily activities, however, was not significantly related to the risk of violent victimization. In terms of the frequency of nighttime activities, Miethe et al. found that individuals with a high frequency of nighttime activities were at an increased risk for property and violent victimization.

Routine Activities and Multilevel Opportunity

At first, researchers examined macro- and microlevel hypotheses derived from routine activities separately. Macrolevel routine activities have been used to explain crime rates, and the routine activities of individuals have been used to explain victimization risk. In more recent years, researchers have begun to explore whether opportunity factors operate at both individual and neighborhood levels to impact victimization risk (e.g., Sampson & Wooldredge, 1987; Wilcox Rountree, Land, & Miethe, 1994). In other words, do the routine activities of the neighborhood in which an individual resides independently influence his victimization risk beyond the effect of his own characteristics and routine activities that leave him vulnerable to crime? For example, leaving one's door unlocked might contribute to victimization risk; living in a neighborhood where it is common to leave one's door unlocked might also contribute to victimization risk. In the first case, one's house can be easily entered if a burglar should try to enter. In the second case, a burglar knows to try to enter the home given the neighborhood norm of leaving doors unlocked. These two factors may both contribute to the risk of victimization for this individual.

In addition, researchers have questioned whether the effects of individual routine activities on victimization risk vary by neighborhood. For example, does leaving one's door unlocked increase risk for burglary victimization to a particular level, regardless of whether one lives in the suburbs or in

the city, or do the neighborhood characteristics *condition* the effect of individual routine activities on victimization risk? Routine activities theory and these types of research questions have inspired further theoretical developments in the area of multilevel opportunity (Wilcox, Land, & Hunt, 2003).

To answer these questions, researchers use data on both the characteristics of the neighborhood that indicate opportunities for crime, as well as the routine activities and other characteristics of the victim that might put him at risk for victimization. To analyze such data, researchers rely on sophisticated multilevel modeling techniques that allow them to determine the effects of individual- and neighborhood-level factors at the same time, as well as the extent to which neighborhood characteristics might condition the effects of individual routine activities on victimization risk.

Complementary Theories, Perspectives, and Applications

Routine activities theory is closely linked to and shares similar assumptions with several other theories and perspectives that are collectively referred to as *environmental criminology*. Unlike traditional criminology, environmental criminology has focused primarily on the proximate environmental and situational factors that facilitate or prevent criminal events. While not discounting individual differences in motivation to commit crime, the primary focus of this area of theory and research has been on understanding the opportunity structures that produce temporal and spatial patterns of crime. In addition to routine activities theory, environmental criminology encompasses the rational choice perspective (e.g., Clarke & Cornish, 1985), situational crime prevention (Cornish & Clarke, 2003), and crime pattern theory (P. J. Brantingham & Brantingham, 1981, 1993; P. L. Brantingham & Brantingham, 1995). Each of these four theories/perspectives provides a unique contribution to the understanding of the criminal event. Their shared assumptions make them complementary, rather than competing, explanations of crime. In addition, a policing approach called *problem-oriented policing* draws heavily from routine activities theory to help understand and interrupt the opportunity structures that produce specific crime problems.

The theories and perspectives reviewed here all point to opportunity blocking for prevention. Environmental criminology and other criminological theories make different predictions about how offenders will respond to blocked opportunities. *Displacement* and *diffusion of benefits*, described later, are two possible offender adaptations to blocked criminal opportunities for crime.

The Rational Choice Perspective

Whereas routine activities theory describes the necessary elements of a criminal event and the controllers who can disrupt that event, the rational choice perspective addresses the

processes by which offenders make decisions. Clarke and Cornish (1985) argued that the decision to offend actually comprises two important decision points: (1) an involvement decision and (2) an event decision. The *involvement decision* refers to an individual's recognition of his or her readiness to commit a crime (Clarke & Cornish, 1985). The offender has contemplated this form of crime and other potential options for meeting his or her needs and concluded that he or she would commit this type of crime under certain circumstances. This involvement decision process, according to Clarke and Cornish, is influenced by the individual's prior learning and experiences. The second decision point—the *event decision*—is highly influenced by situational factors. Situations, however, are not perceived the same way by all people; instead, the person views them through the lens of previous experience and assesses them using his or her information-processing abilities (Clarke & Cornish, 1985). At times, the information used to make decisions is inaccurate, with judgment being clouded by situational changes, drugs, and/or alcohol. Although this model describes involvement and event decisions as two discrete choices, in reality the two may happen almost simultaneously.

Over time, the involvement decision continues to be shaped by experience. Positive reinforcement from criminal events can lead to increased frequency of offending. The individual's personal circumstances might change to further reflect his or her readiness to commit crime. For example, Clarke and Cornish (1985) pointed to increased professionalism in offending, changes in lifestyle, and changes in network of peers and associates as personal conditions that change over time to solidify one's continual involvement decision. Conversely, an offender may choose to desist in response to reevaluating alternatives to crime. This decision could be influenced by an aversive experience during a criminal event, a change to one's personal circumstances, or changes in the larger opportunity context (Clarke & Cornish, 1985). Both the involvement and event decisions can be viewed as rational in that they are shaped by the effort, risks, rewards, and excuses associated with the behavior.

Situational Crime Prevention

Situational crime prevention is grounded in the rational choice perspective in that it manipulates one or more elements to change the opportunities for crime and in turn change the decision making of potential offenders. In terms of routine activities theory, situational crime prevention can be viewed as the mechanisms by which controllers (i.e., guardians, place managers, and handlers) discourage crime. Over the past few decades, researchers and criminal justice practitioners alike have used the techniques of situational crime prevention to understand crime problems, develop interventions, and evaluate the effectiveness of those interventions. Situational crime prevention was designed to address highly specific forms of crime by systematically manipulating or managing the immediate environment in as permanent a way as possible, with the purpose of reducing

opportunities for crime as perceived by a wide range of offenders (Clarke, 1997). Situational crime prevention techniques focus on effectively altering opportunity structures of a particular crime by increasing the efforts, increasing the risks, reducing the rewards, reducing provocations, and removing excuses (Cornish & Clarke, 2003). On its face, situational crime prevention techniques change the event decision by altering the offender's perceptions of a specific criminal opportunity. However, it should be noted that an offender's experience during a criminal event directly affects his or her continual involvement decision over time. Blocked opportunities not only prevent an impending criminal event but might also nudge the offender in the direction of abandoning crime.

Crime Pattern Theory

Crime pattern theory provides a framework of environmental characteristics, offender perceptions, and offender movements to explain the spatially patterned nature of crime. It is compatible with routine activities theory because it describes the process by which offenders search for or come across suitable targets. P. J. Brantingham and Brantingham (1981) began with the premise that there are individuals who are motivated to commit crime. As these individuals engage in their target selection process, the environment emits cues that indicate the cultural, legal, economic, political, temporal, and spatial characteristics/features of the area. These elements of the environmental backcloth are then perceived by the offender, and he or she interprets the area as being either favorable or unfavorable for crime. Over time, offenders will form templates of these cues on which they will rely to interpret the environment during target selection.

P. J. Brantingham and Brantingham (1993) argued that one common way offenders encounter their targets is through overlapping or shared activity spaces; in other words, offenders come across their targets during the course of their own routine activities, and therefore the locations of these activities, as well as the routes traveled to these locations, will determine the patterning of crime across space. Brantingham and Brantingham referred to the offender's home, work, school, and places of recreation as *nodes*. The routes traveled between these nodes are referred to as the *paths* of the offender. Finally, *edges* are those physical and mental barriers along the locations of where people live, work, or play. The offender is most likely to search for and/or encounter targets at the nodes, along paths, and at the edges, with the exception of a buffer zone around each node that the offender avoids out of fear of being recognized. Brantingham and Brantingham argued that crime events will thus be clustered along major nodes and paths of activity, as well as constrained by edges of landscapes. The spatial patterns of crime will reflect these two features: the environmental backcloth and the heavily patterned activity paths, nodes, and edges. In addition, Brantingham and Brantingham noted that some places have particularly high levels of crime because of the characteristics of the activity and people associated with it.

Specifically, they suggested that some places are *crime generators*, in that people travel to these locations for reasons other than crime, but the routine activities at these places provide criminal opportunities. Conversely, other places are *crime attractors* in that their characteristics draw offenders there for the purpose of committing crimes.

Problem-Oriented Policing and Problem Analysis

Police agencies use routine activities theory as part of problem-oriented policing. In addition, researchers, city planners, nonprofit organizations, and private citizens follow the same problem analysis process used in problem-oriented policing to understand and prevent crime problems. Problem-oriented policing (Goldstein, 1979) is a proactive policing approach that focuses on systematically addressing problems that produce numerous crime incidents and calls for service to the police, instead of reacting to and treating each call for service in isolation. The problem, rather than the individual crime incident, becomes the unit of work for the police. Problems are a form of crime pattern. Within problem-oriented policing, police work to define, understand, and prevent problems that generate numerous crime incidents and citizen calls to the police.

Problem-oriented policing is implemented through the use of the SARA process—Scanning, Analysis, Response, and Assessment. The police *scan* crime data and calls for service to identify crime patterns that are produced by a problem. A problem should be narrowly defined; that is, instead of broadly identifying a “theft problem,” it is important to be specific and identify the problem as “theft of shoes from unsecured lockers at the roller rink during after-school hours.” The police then *analyze* the problem to understand its characteristics and causes. The crime triangle depicted in Figure 32.1 is often used to organize the analysis; police collect information on all sides of the triangle, not just on offenders. On the basis of this analysis, the police develop *responses* to prevent future crimes. These responses go beyond traditional police tools of arrest and citation to include less traditional tools that may help disrupt the causes of the problem. These less traditional approaches involve one or more of the three types of controllers discussed earlier. Finally, police *assess* the overall impact of the response and alter the process accordingly, depending on the results.

It is during the SARA process that routine activities theory can be applied for prevention. Problem-oriented policing complements research that indicates that crime is not randomly distributed (e.g., Eck, Clarke, & Guerette, 2007); instead, some people are repeatedly victimized, some places are repeatedly the sites of crime, and some people repeatedly offend. Eck (2001) suggested that not only does routine activities theory describe the six elements of a crime event but also that specific types of repeat crime and disorder problems can be connected to these elements. Using the terms *wolf*, *duck*, and *den*, problems of repeat victimization, repeat places, and repeat offending can be seen as a function

of both the routine activities of potential offenders, victims, and/or places as well as the absence or ineffectiveness of potential handlers, guardians, and/or managers. This in turn sheds light on what steps should be taken to prevent future crimes stemming from the same problem. A “wolf” problem reflects the repeated actions of an offender or group of offenders, with absent or ineffective handlers. A “duck” problem is one in which the same individual or group is repeatedly victimized; this repeat victimization can be attributed to both the routine activities and characteristics of the victims as well as the absence of capable guardians. A “den” problem is one in which a place is both attractive to targets and offenders while also having weak or absent place managers. The repeat-place problem in which an apartment building is consistently the site of police calls for service might indicate that place managers, such as the landlord or building manager, need to be encouraged or coerced to take control of the problem. In other words, using routine activities theory during problem analysis reveals the absent or ineffective controller who needs to be empowered or held responsible. Furthermore, it might also reveal the activity patterns that systematically produce the opportunity for the crime and suggest points of intervention.

Displacement and Diffusion of Benefits

One common concern when implementing opportunity blocking crime prevention strategies is that crime will simply be *displaced*. In other words, a particular crime event that appears to be prevented is inevitably displaced to another time, place, and/or victim. Different theories of crime make different predictions about the likelihood of displacement in response to blocked criminal opportunities (Clarke, 1997). Traditional criminological theories of offenders suggest that displacement is inevitable when an opportunity for crime is blocked. This prediction is consistent with the assumptions that (a) only offenders matter because (b) crime opportunities are infinite and evenly spread across time, space, and people. These theories suggest that motivated offenders will adapt and simply move on to another available opportunity. Conversely, opportunity theories such as routine activities theory suggest that displacement is possible, but only to the extent that other available criminal opportunities have similar rewards without an increase in costs to the offender (Clarke, 1997). This prediction is consistent with routine activities theory’s focus on opportunity. Opportunities are not assumed to be infinite and equally gratifying to the offender. The likelihood of displacement, therefore, is tied to the relative costs and benefits of alternative crime opportunities. If an offender is unaware of alternative crime opportunities or these alternatives are very unattractive (i.e., they are difficult, risky, or less rewarding), then displacement is unlikely.

There is another possible offender adaptation to crime prevention strategies. Not only might displacement not occur, but also it is possible that the gains from a strategy

might extend beyond those crimes that were directly targeted by the strategy. One explanation for this *diffusion of benefits* is that offenders, uncertain of the actual scope of a particular strategy, refrain from offending in situations beyond the scope of the strategy (Clarke & Weisburd, 1994). Opportunity theories, such as routine activities theory, predict that there may be a diffusion of benefits in response to opportunity blocking if other crimes share similar opportunity structures with those crimes targeted by the strategy. Conversely, dispositional theories of crime generally cannot account for diffusion of benefits.

Environmental criminologists have dedicated considerable attention to the issue of displacement, producing a body of research on displacement that suggests that displacement is not inevitable, nor is it complete when it does occur. Furthermore, there is evidence to suggest that there is sometimes a diffusion of benefits in response to crime prevention strategies. Hesselting (1994) reviewed 55 published articles and reports suggesting that displacement does not appear to be inevitable. When it does occur, it tends to be limited. Of the 55 studies Hesselting reviewed, 22 found no sign of displacement. Six of these studies reported some diffusion of benefits to crimes beyond those directly targeted. Of the 33 studies that reported displacement, no study found complete displacement. The displacement that did occur generally reflected a shift in time, place, target, or tactic for the offender.

Future Directions

Although routine activities theory has informed a wealth of research to date, there are still many avenues of research yet to be exhausted. Several areas of research informed by routine activities theory are in their early stages. Guardianship is one of the earliest concepts within routine activities theory, yet there is relatively little understanding of the various forms of guardianship, when and where these forms are effective, and the means by which guardianship reduces crime. On a superficial level, guardianship appears to deter offending by increasing the likelihood the offender will be detected and sanctioned. As many guardians have limited authority, skills, or means to detect and sanction offenders, one may wonder whether (a) guardianship can be based on some other mechanism other than deterrence or (b) many of the examples of guardianship we assume are effective are really guarding; perhaps other things are preventing crime. More research needs to examine this topic.

Another area for research is the concepts of place manager and management. Recently, the Madensen ORCA model of management unpacks these concepts. It states that place management consists of four activities: (1) the Organization of physical space, (2) the Regulation of conduct, (3) the Control of access, and (4) the Acquisition of resources. The study of management and its influence on crime will have to address all four activities and merge crime science with business and management science.

Handlers have received very little attention by routine activity researchers, relative to guardians and managers, yet recent evidence suggests that they may have powerful influences on crime and crime patterns. Tillyer (2008) showed how the concept of handling can be used to reduce a wide variety of crime, from minor juvenile delinquency to group-related homicide.

Crime concentrations appear when none of the controllers is present or effective and offenders meet targets, but why is these controllers absent or ineffective? One answer might be that the controllers whom Rana Sampson (1987), a consultant on problem-oriented policing, calls *super controllers* are not exerting sufficient or the right influence on the controllers. Super controllers are people and institutions that control controllers. For example, a bartender and bar owner are managers, and the state liquor regulatory agency is one of their super controllers. Foster parents are handlers of children put in their care. Child welfare agencies act as their super controllers. A security guard is a guardian, and the company that hired the guard is a super controller. There is almost no research in this area, although it holds great promise for understanding crime and developing prevention.

Routine activities theory focuses on offenders making contact with targets at places. Some crimes, however, involve “crime at a distance.” Mail bombers, for example, do not come close to their targets. Internet fraudsters are able to steal from victims from anywhere in the world. Either routine activities theory is limited to place-based crimes or it needs revision. Eck and Clarke (2003) suggested that substituting *system* for *place* solves the problem. Systems connect people, and they are governed by managers. The mail bomber uses the postal system to contact his victim, and the Internet fraudster uses a system of networked computers. Research on routine activities in systems is in its infancy.

Although it is possible to study the contribution of elements of routine activities theory to the study of crime, it is impossible to empirically study all the elements interacting to create crime patterns. That is because even our best sources of information contain data on only one or two of the actors involved: offenders, targets, handlers, guardians, and managers. Also, the best data available are often highly aggregated and rife with errors. Computer simulations of crime patterns, however, provide a method for exploring how these parts interact in a dynamical system. This is a very new area of research that has spawned simulations of a wide variety of crime types: drug dealing, burglary, robbery, welfare fraud, and others (Liu & Eck, 2008).

Conclusion

To summarize, routine activities theory is a theory of crime events, which distinguishes it from a majority of criminological theories that focus on explaining why some people commit crimes. Although routine activities theory was initially

used to explain changes in crime trends over time, it has been increasingly used much more broadly to understand and prevent crime problems. Routine activities theory has guided research designed to understand a range of phenomena, including crime trends over time, distributions of crime across space, and individual differences in victimization. It also has been used in conjunction with many crime control strategies, including problem-oriented policing and problem analysis. Despite the broad applicability of the theory to date, there are numerous directions for future research. Examples include further research on the controllers of crime as well as the super controllers.

Note

1. Cohen and Felson (1979) calculated their household activity ratio by summing the number of married, husband-present female labor force participant households and the number of non-husband-wife households and then dividing by the total number of households in the United States.

SELF-CONTROL THEORY

TRAVIS C. PRATT AND JONATHON A. COOPER

Arizona State University

Self-control theory—often referred to as *the general theory of crime*—has emerged as one of the major theoretical paradigms in the field of criminology. This is no small feat, given the diversity of criminological perspectives that exist in general and the ever-growing roster of recently sprouted control theories in particular. To be sure, scholars have developed models of formal social control (e.g., rational choice/deterrence theories), informal social control (e.g., social disorganization, collective efficacy), indirect control (e.g., social bond theories), power control, and so on, yet self-control theory has arguably become the most influential member of the control theory family since its publication by M. R. Gottfredson and Hirschi in 1990. Accordingly, the purpose of this chapter is fourfold: (1) to provide an overview of the core theoretical propositions specified by self-control theory (i.e., what causes crime, according to this perspective?); (2) to critically assess its empirical status (i.e., what does the body of studies testing this theory have to say about the degree to which Gottfredson and Hirschi were right?); (3) to highlight the criticisms leveled against it (i.e., where do there appear to be “holes” in the theory?); and, finally, (4) to specify directions for future research within the self-control tradition.

Self-Control as a General Theory of Crime

Gottfredson and Hirschi (1990) sought to accomplish a number of goals when they formulated their theory of self-control

and crime. At the most fundamental level, they reinterpreted and reintroduced the classical school of thought in combination with a positivistic methodological orientation. More specifically, they intended to create a theory on the basis of what was known from research about criminal events and criminals rather than to rehash empirically vague sociological theories. Finally, they sought to develop a theory that would explain crime generally, that is, across times, persons, and situations.

To these ends, their general theory constituted a reassertion of the classical school’s initial contention that individuals seek personal pleasure while avoiding pain (Beccaria, 1764/1963). In short, people are motivated by self-interest. Furthermore, positivism attempts to understand human behavior through the scientific method. In its use of the scientific method, however, Gottfredson and Hirschi (1990) claimed that positivism went too far in creating needless disciplinary fissures, redundant theories, and contrived typologies. Moreover, positivist criminology confounds crime, delinquency, and other antisocial behavior. Gottfredson and Hirschi suggested that, by combining the methodological approaches handed down from positivist science, but in using the classical school as an overriding framework, criminologists could arrive at a general theory of crime.

Doing this, however, would require a good look at criminal acts and criminals, something that Gottfredson and Hirschi (1990) claimed criminologists had not really done. They suggested that criminologists have instead focused their efforts on explaining crime in light of artificial statutory

definitions and a rejection of individual choice. Accordingly, this has led to an abundance of theories that have succeeded in accounting for only a small proportion of the variance in crime; blindness to deviant behaviors that are analogous to crime; and misapprehension of criminals as being specialists, as opposed to generalists. Thus, to develop the general theory, Gottfredson and Hirschi started by looking at what criminologists *do* know about crime and criminals. Their research revealed that criminal events are generally based on immediate gratification or removal of an irritant, are easy, and are varied. Similarly, they found that criminals displayed characteristics similar to crime events: Criminals were found among individuals seeking immediate and easy gratification and whose behavior included numerous types of crime and other deviant behaviors. Gottfredson and Hirschi therefore claimed that the crime and the criminal were contiguous elements.

At the heart of criminal events and criminals was one stable construct: low self-control. This, Gottfredson and Hirschi (1990) claimed, explained criminal acts and behavior across time, gender, ethnicity, and crime types. Beyond crime, low self-control was further evident in behavior analogous to criminal acts, such as antisocial (but not illegal), deviant, and risk-taking behavior (e.g., smoking, excessive drinking, riding a bike without a helmet, skydiving). This, according to Gottfredson and Hirschi, constituted a general theory of crime: Low self-control was the general, antecedent cause of forceful/fraudulent acts “undertaken in pursuit of self-interest” (p. 15).

The Context of the 1980s

Lilly, Cullen, and Ball (2007) declared that Gottfredson and Hirschi’s (1990) theory has remained a robustly empirically supported criminological theory throughout the almost two decades since *A General Theory of Crime* was published. Lilly and colleagues ascribed such popularity to the theory’s parsimonious nature; the combative stance it takes against structural theories, which draws attention from the academy; and the fact that it is elegantly testable. The theory’s popularity can also be explained in light of the context in which it was developed: the 1980s, which witnessed a renewed interest in individual-level explanations of criminal behavior (Pratt & Cullen, 2005). This renewal coincided with a conservative takeover of criminal justice policy throughout the United States, owing much to the reaction/response to the prior two decades of secularism, hedonism, and social welfare programs (Pratt, 2009). During the 1960s and 1970s, it was common within the university environment to question the status quo and social order. Race, class, and gender inequalities were increasingly being discussed and debated, and crime became linked to such inequalities, as well as to inequalities associated with legitimate social and economic opportunities. Crime was also explained in terms of the state’s response to criminals. It was during this time that labeling and Marxist theories were popular among criminologists (Lilly et al., 2007).

The ideological pendulum swung most forcefully at the beginning of the 1980s, with the election of Ronald Reagan and the institutionalization of the “silent majority’s” agenda. This movement was characterized by patriotism, hard work, religion, and the role of the individual in directing his or her affairs. This time was also characterized by a mistrust of secular culture and a lack of patience with social welfare programs and policies (Murray, 1984). In this environment, several conservative values-based criminological theories proliferated that emphasized choice and agency among individuals in the commission of criminal acts and that shifted the focus of the criminal justice system toward a punitive orientation. Furthermore, emphasis was placed on the role of families as agents of social control. It was in this context that Gottfredson and Hirschi (1990) proclaimed that they “have for some time been unhappy with the ability of academic criminology to provide believable explanations of criminal behavior” (p. xiii).

The Nature of Low Self-Control

Gottfredson and Hirschi (1990) defined *self-control* as “the tendency of people to avoid criminal acts whatever the circumstances in which they find themselves” (p. 87). Thus, low self-control can essentially be defined as a lack of that tendency. Individuals with low self-control are characterized as impulsive, insensitive, physical, “risk-taking, short-sighted, and nonverbal” (p. 91). In short, these are “factors affecting calculation of the consequence of one’s acts” (p. 95). Gottfredson and Hirschi further elaborated on the behavior and attitudes of individuals with low self-control, stating that such individuals have a here-and-now orientation; they lack diligence, tenacity, and persistence; and they are self-centered, indifferent, and insensitive. Furthermore, people who lack self-control tend to exhibit adventuresomeness and are active and physical; they also generally have unstable families, friendships, and professional lives. Finally, individuals with low self-control can be characterized as having a minimal tolerance for frustration; they tend to respond to conflict physically rather than verbally; and they do not necessarily possess or value verbal, academic, cognitive, or even manual skills. Because of these characteristics, individuals with low self-control may not only be involved in crime, but they may also be involved in various other risky behaviors, such as smoking, doing drugs, and engaging in illicit sex. According to Gottfredson and Hirschi, low self-control is the stable construct that ties all of these characteristics, attitudes, and behaviors together. It is a construct that is recognizable in childhood, prior to the age of accountability, and is stable throughout the life course.

The “Development” of Low Self-Control

Gottfredson and Hirschi (1990) contended that, ultimately, one does not develop low self-control. Instead, possessing low self-control is more a matter of having not

developed self-control as a young child. Accordingly, low self-control manifests itself in the “absence of nurturance, discipline, or training” (p. 95). Stated otherwise, “The causes of low self-control are negative rather than positive; self-control is unlikely in the absence of effort, intended or unintended, to create it” (p. 95). Here Gottfredson and Hirschi are stating that if a person does not develop self-control, the default is low self-control. Acquiring self-control is a matter of socialization.

Gottfredson and Hirschi (1990) placed the onus of this socialization primarily on parents. A child with low self-control then becomes the product of “ineffective child-rearing” (p. 97). Specifically, the authors stated that consistent supervision and discipline, coupled with affection, results in the proper development of self-control. They noted that several things may impede this socialization process, however, including parents who may not feel affection toward their children or who lack the time or energy to devote to supervision, and parents who may not see problem behavior for what it is and who may, having witnessed and processed their child’s inappropriate behavior, not be so inclined to punish them. Such situations may become exacerbated when parents engage in behavior indicative of low self-control themselves.

It is important to note that this perspective differs in a fundamental way from Hirschi’s (1969) social bond theory. Specifically, Hirschi’s original social bond theory held that, once social bonds were formed between a child and parents, parents would then be able to indirectly control the behavior of their children. Put differently, once the bond was established—even if the child was quite young—the child would voluntarily control his behavior even in the absence of a parent watching over him, because he would feel the psychological presence of the parental guardian, who would be disappointed in the child should he misbehave. For Gottfredson and Hirschi (1990), however, the faith in indirect control was abandoned in favor of a model that emphasized the importance of direct parental control; that is, parents should not expect children to control themselves (at least not prior to the formation of self-control, which should happen by around age 8–10), but instead it is only through direct supervision and control that self-control may be instilled. In the end, Gottfredson and Hirschi conceived of self-control as a singly unitary factor that is formed early in life through effective parenting, fixed by a relatively young age, stable over the life course, and solely responsible for explaining the variation in criminal/deviant behavior across individuals.

Self-Control and Crime

Classical theories of crime did not assume that some individuals were more predisposed to criminal conduct than others; instead, such theories assumed that it was one’s location in the social system, or whether one understood the nature of sanctions, that determined whether one was a criminal. Criminals and noncriminals alike had one

purpose in mind: to enhance their exposure to pleasure and to reduce their exposure to pain. Therefore, classical criminologists sought to combat crime by increasing painful sanctions through the legal and moral systems of the time. Gottfredson and Hirschi (1990, p. 85) therefore referred to classical theories as *theories of social control*.

On the other hand, positivism did assume differential propensities to commit crime; that is, that criminals and noncriminals were different in some fundamental respect (be it biological, psychological, economic, or sociological). Early positivists, however, denied the impact of social location, assuming that criminal propensities remained stable regardless of social location. Gottfredson and Hirschi’s (1990) answer to these opposing views was to join them under the category of low self-control; that is, they explained crimes in terms of both individual propensity (positivist theory) and in terms of the desire to enhance pleasure while reducing pain (classical theory). One’s ability to avoid criminal acts (keeping in mind Gottfredson and Hirschi’s expansive definition of crime) and analogous behaviors are dependent on his or her level of self-control in light of environmental contingencies. Crime, and its analogous behavior, is simply a manifestation of low self-control.

To illustrate, Gottfredson and Hirschi (1990, pp. 89–90) sifted through a number of attitudes, behaviors, and characteristics of individuals with low self-control and demonstrated how each relates to crime. First, low self-control is associated with having a present orientation, as opposed to being able to defer gratification. Accordingly, individuals with low self-control are likely to commit crimes because such acts amount to the immediate gratification of one’s desires. Similarly, those with low self-control tend to lack diligence, tenacity, and persistence. Again, crime events are easy and represent a simple means of gratifying one’s appetites while not requiring pesky or inconvenient long-term planning or commitment. Low self-control is also associated with adventurous, physical activities, making such individuals especially prone to crime. Individuals with low self-control generally have shaky marriages, unstable friendships, and spotty job histories. This demonstrates an inability on their part to form long-term plans, which is equally amenable to the short-term nature of crime and analogous conduct. Similarly, the fact that individuals with low self-control are more likely to engage in such analogous behavior indicates a preference for immediate pleasure and an inability to defer gratification. Finally, low self-control is associated with minimal tolerance thresholds and a self-centered, indifferent attitude, which allows criminals to remove themselves from the harm they do to their victims and gives them the justifications for committing crimes (i.e., in an effort to remove frustrations and pains).

Gottfredson and Hirschi (1990) noted that the criminological literature demonstrates that, for the most part, offenders are generalists, not specialists (Blumstein, Cohen, Roth, & Visher, 1986; see also Sullivan, McGloin, Pratt, & Piquero, 2006). This makes sense in light of the concept of

low self-control: Individuals with low self-control are unable to focus to the extent required to specialize in one area, even within crime. This is evident in the fact that individuals with low self-control do not maintain marriages, jobs, and other activities that require commitment and diligence. Furthermore, Gottfredson and Hirschi considered crime to be simple and easy in general, begging the question as to why one would specialize when it is easier and quicker to generalize in one's offending preferences. Finally, that offenders generalize is evidenced by Gottfredson and Hirschi's contention that individuals with low self-control engage in criminal, risky, and antisocial behavior because opportunities to engage in such behavior are constantly present. Furthermore, according to Gottfredson and Hirschi, low self-control predates and predicts all other correlates of criminal behavior. Moreover, Gottfredson and Hirschi maintained that their theory can robustly predict criminal behavior across gender, time, sex, and ethnicity. They ultimately claimed that their theory succeeds in revitalizing the classical assertion that pleasure and harm avoidance guide human behavior, including criminal behavior.

Empirical Status of the General Theory of Crime

Gottfredson and Hirschi's (1990) theory makes many testable claims, some of which have weathered the storm of empirical criticism, others of which remain wanting. In general, however, the general theory of crime has remained robustly supported across multiple types of samples, methodologies, and variations in measurement, in terms of its central claim that low self-control predicts criminal and analogous behaviors. In Gottfredson's (2006) most recent review of the literature, he concluded that low self-control has remained predictive across gender, location, age, race, offense type, offenders, analogous behavior, and time. Lilly et al. (2007) further noted that the theory has received extensive support across individual studies, a comprehensive meta-analysis, and a full narrative literature review. Akers and Sellers's (2004) review also found substantial support for self-control theory across cultures, explaining anywhere from 3.0% to 19.0% of the variation in criminal behavior.

The most quantitatively sound review of the general theory of crime was conducted by Pratt and Cullen (2000), who used meta-analytic techniques to ascertain the empirical status of self-control theory. The authors' data came from 21 peer-reviewed published articles, for a total of 126 effect size estimates, across 17 individual data sets, and a total of 49,727 individual cases. To control for measurement effects, the researchers coded for whether studies had used behavioral versus attitudinal measures of self-control; when attitudinal measurements were used, the studies were further coded to control for whether the researchers used Grasmick, Tittle, Bursik, and Arneklev's (1993) extremely popular self-control scale. Finally, Pratt and Cullen controlled for whether studies had used longitudinal versus cross-sectional

research designs. In terms of the predictive value of low self-control as it relates to crime, they found that the effect size of low self-control regularly exceeded 0.20, net of variables specified by other theories and methodological considerations. Furthermore, the meta-analysis results supported the theory's contention that crime and analogous behavior can be predicted from a single source (low self-control) across race, sex, age, and community. It is important to note that Pratt and Cullen found that similar effect sizes were found across behavioral and attitudinal scales of self-control and regardless of whether attitudinal scales invoked Grasmick et al.'s indicators of low self-control. These findings go a long way toward responding to the criticism that self-control studies that use behavioral measurements are inherently tautological (i.e., that the use of behavioral indicators of low self-control—in short, deviant yet legal behaviors—to predict other deviant yet illegal behaviors merely amounts to bad behavior being related to bad behavior, a finding of little interest to criminologists).

Beyond the low self-control–criminal behavior link, Pratt and Cullen's (2000) meta-analysis failed to support at least two of Gottfredson and Hirschi's (1990) contentions, namely, (1) that the self-control–crime relationship would hold across both cross-sectional and longitudinal studies and (2) that low self-control represents a general explanation of behavior. Gottfredson and Hirschi argued that because self-control is invariant across the life course, cross-sectional research designs (which represent the bulk of social science research) were adequate for testing self-control theory. Pratt and Cullen, however, found that the effect sizes for self-control were significantly weaker in longitudinal studies compared to those from cross-sectional studies. Further, Gottfredson and Hirschi explicitly stated the irrelevance of other criminological theories because of their assumption that self-control was a precursor to all other criminogenic factors. Even so, Pratt and Cullen found that variables specified by social learning theory—in particular, deviant peer influences and antisocial attitudes—not only had an impact on crime independent of self-control but also increased the explanatory power of each study's overall statistical models. This strongly suggests that Gottfredson and Hirschi's general theory of crime may not be so general.

Indeed, much of the research reviewed by Akers and Sellers (2004) and by Lilly et al. (2007) found Gottfredson and Hirschi's (1990) claims beyond the low self-control–criminal behavior connection wanting. For example, Akers and Sellers found mixed results for the hypothesis concerning the relative stability of self-control over the life course, with some research suggesting its relative stability, others indicating its variability, and yet others finding it to be at once both stable and variable. They found similar results among the research exploring the extent to which low self-control is a unidimensional factor. Furthermore, they found research suggesting that, in regard to low self-control's causes, those proposed by Gottfredson and Hirschi were predictive, but not independent other factors, such as fair discipline and parental acceptance. Similarly, Lilly et al.

found support for sources of low self-control outside of the family, including neighborhood-level factors as well neurobiological factors—findings that are reviewed at length later in this chapter.

Ultimately, the central proposition of the general theory of crime—that low self-control predicts criminal, delinquent, antisocial, and analogous behaviors—holds across several studies, methodologies, samples, and measurements. Research has not, however, supported Gottfredson and Hirschi's (1990) claim to having authored a “general” theory. Instead, it appears that their theory of criminal behavior, based on levels of low self-control, specifies a vital predictor of criminal behavior that is necessary for criminological models so as to avoid misspecification but is nevertheless far from the sole predictor of criminal and deviant behavior.

Critiques of Self-Control Theory

Scholars have taken issue with a number of tenets of Gottfredson and Hirschi's (1990) theory, from its seeming inability to explain white-collar offending to problems with how researchers should go about measuring self-control. Others have called attention to the potential problem of rectifying the explanation of crime—that such behavior is due to a single latent trait that is stable over time—with the well-known age-crime curve (the observed empirical pattern in which adults tend to reduce their rate of criminal behavior following a peak in their late teens). Although these debates are certainly important in their own right and will most definitely continue into the future, Gottfredson and Hirschi face their most serious challenges with regard to the following: (a) the influence of adult social bonds in the criminal desistance process, (b) the enduring importance of deviant peer influences on one's criminal behavior, and (c) the sources of self-control.

Adult Social Bonds and Life Course Criminology

Gottfredson and Hirschi (1990) were clear in their assertion that changes in one's social circumstances from childhood, to adolescence, to early adulthood and beyond are irrelevant to the explanation of crime. In particular, according to Gottfredson and Hirschi, the age-crime curve cannot be predicted by traditional sociological variables, such as marriage and work. Instead, the authors claimed that the attachments to employment and spouses are merely consequences of self-control; that is, people with higher levels of self-control are more likely to self-select into healthier relationships with work and family. That such factors are, in turn, associated with reductions in criminal behavior therefore comes as no surprise to Gottfredson and Hirschi. Indeed, one would expect relationships to exist between an adult's bonds to social conventions (e.g., marriage and work) and criminal behavior, because both emerge from the common source of self-control.

Recent developments in life course theory and research, however, paint a much different picture. To be sure, the work conducted by Sampson and Laub (1993; see also Laub & Sampson, 2003) has taken levels of self-control into account in an assessment of the role that adult social bonds play in the criminal desistance process. Specifically, their study of men's criminal behavior up to age 70 revealed that, independent of one's level of self-control, attachment and involvement with prosocial activities through employment and marriage significantly reduce levels of offending. Thus, although it is certainly true that individuals with lower levels of self-control find it more difficult to form the kinds of social relationships necessary for a stable work and family life, those who do nonetheless do a better job of controlling whatever criminal impulses they were previously in the habit of letting loose. These findings are particularly challenging of Gottfredson and Hirschi (1990) because they indicate that the explanation of criminal behavior over the life course clearly requires more than the specification of a single variable that is assumed to be fixed within individuals by age 10.

The Enduring Importance of Deviant Peers

In extending the importance of understanding the context in which people (both children and adults) live their lives, scholars have also taken issue with Gottfredson and Hirschi's (1990) rather bold assertion that deviant peer influences—a staple of criminology for years—are also irrelevant to the explanation of crime. Like the influence of adult social bonds, Gottfredson and Hirschi argued that individuals with low self-control will seek each other out because of their common interests in engaging in risky behaviors that provide immediate gratification. Thus, the concept of the deviant peer group, which has been a mainstay in the social learning tradition in criminology for at least six decades, is merely the consequence of self-control, according to Gottfredson and Hirschi.

The problem again, however, comes when the empirical evidence is examined. In particular, Pratt and Cullen's (2000) meta-analysis of the self-control literature found that the relationship between deviant peers and one's own criminal behavior was every bit as strong as that between self-control and crime. These peer effects stood up even in studies that included statistical controls for self-control. Thus, Gottfredson and Hirschi's (1990) claim that peer influences should not matter once self-control is taken into account is inconsistent with the social scientific evidence. Instead, the research indicates that both self-control and deviant peer influences are important to the explanation of criminal behavior.

Sources of Self-Control

Although the link between self-control and crime/deviance has been consistently demonstrated empirically, what is less

clear at this point is how self-control is established within individuals. As stated earlier, the primary explanation regarding the “cause” of self-control according to Gottfredson and Hirschi’s (1990) involves a parenting thesis. In short, Gottfredson and Hirschi contended that self-control will develop in children through effective parenting, whereby parents who monitor their kids’ behavior, recognize deviant behavior when it happens, and punish such behavior consistently will produce in their children the internal control mechanisms necessary for resisting the temptations that criminal and deviant behavior provide. Support for this proposition is certainly present (see, e.g., Hay, 2001; McGloin, Pratt, & Maahs, 2004; Perrone, Sullivan, Pratt, & Margaryan, 2004); nevertheless, empirical evidence has emerged indicating that the processes that establish individuals’ levels of self-control are more complex than those specified by Gottfredson and Hirschi. This problem is beginning to emerge as perhaps the most serious challenge to the validity of Gottfredson and Hirschi’s theory, and research related to this question comes from multiple fronts.

First, Gottfredson and Hirschi (1990) downplayed the possibility that low self-control has a genetic or biological component. For example, following their analysis of adoption studies, they argued that this research provides “strong evidence that the inheritance of criminality is *minimal*. . . . we conclude that the ‘genetic effect’ . . . is near zero” (p. 60). They also noted that “obviously, we do not suggest that people are born criminals, inherit a gene from criminality, or anything of that sort. In fact, we explicitly deny such notions” (p. 96). Gottfredson and Hirschi nevertheless raised the possibility that “individual differences may have an impact on the prospects for effective socialization (or adequate control)” (p. 96), yet they quickly countered that such differences would be important only if they resulted in problematic responses from parenting, once again echoing the importance of parental efficacy in the development of self-control.

A number of criminologists, however, fundamentally disagree with this position and have instead adopted a more interdisciplinary (as opposed to strictly sociological) view of the sources of self-control—one that recognizes the intellectual contributions of psychology and biology to the understanding of human behavior (see, e.g., Pratt, Cullen, Blevins, Daigle, & Unnever, 2002; Pratt, McGloin, & Fearn, 2006). Accordingly, despite the evidence of a parenting–self-control link, these scholars have noted a potential model misspecification problem with this line of research. In particular, much of this work has failed to consider potential biological and neuropsychological sources of self-control independent of (and in conjunction with) parental sources.

To that end, research has begun to emerge that examines these alternative sources of low self-control (Pratt, 2009). As such, two primary conclusions can be reached from this body of work. First, indicators of biological predisposition (e.g., attention deficit hyperactivity disorder; indicators of neuropsychological deficits, such as low birth weight and

low cognitive ability) are significantly related to levels of self-control independent of measures of effective parenting (McGloin, Pratt, & Piquero, 2006; Unnever, Cullen, & Pratt, 2003; Walsh, 2002). Second, controls for such biological and neuropsychological factors tend to partially mediate—and in some cases fully mediate—the effect of parenting on the development of self-control (see, e.g., Wright & Beaver, 2005). Taken together, this research indicates that certain biological and neuropsychological risk factors need to be considered in the formation of self-control.

Another line of research into the sources of self-control highlights the interrelationships among community context, parenting, and the development of self-control. Specifically, to the extent that communities act “as a complex system of friendship and kinship networks and formal and informal associational ties rooted in family life and ongoing socialization processes” (Kasarda & Janowitz, 1974, p. 329), it seems particularly important to focus on how different types of neighborhoods influence parenting behavior and, in turn, the development of self-control in children. Researchers have begun to do just that. The first study in this tradition was Pratt, Turner, and Piquero’s (2004) analysis of data drawn from the National Longitudinal Survey of Youth, which found that conditions of neighborhood deprivation significantly influenced measures of parental monitoring and socialization. Furthermore, such neighborhood conditions directly affected the development of self-control in children independent of the measures of parental efficacy. A subsequent study by Hay, Fortson, Hollist, Altheimer, and Schaible (2006) went a step further and found a significant interaction between neighborhood conditions and parental efficacy on the development of self-control. This work clearly indicates that community context is yet another factor that must be seriously considered by scholars with regard to the development of self-control in children.

Furthermore, although attributing the main sources of self-control to parental socialization, Gottfredson and Hirschi (1990) also acknowledged that school has certain advantages to socializing children. First, schools, and teachers in particular, have the ability to monitor several students at one time. Second, because of their interest in maintaining a healthy educational environment, teachers are in a good position to recognize antisocial behavior when children are exhibiting it. Third, many schools and teachers are given the authority to maintain order and to implement effective discipline. Therefore, Gottfredson and Hirschi suggested that “like the family, the school in theory has the authority and the means to punish lapses in self-control” (p. 105). Also, as Denise Gottfredson (2001) observed, “Schools have the potential to teach self-control and to engage informal social controls to hold youthful behavior in check” (p. 48).

Empirical work has recently emerged that has tested these various propositions. Turner, Piquero, and Pratt’s (2005) analysis of the National Longitudinal Survey of Youth data revealed two conclusions along these lines. First, indicators of *school socialization* (which closely

resembled typical parenting measures associated with the monitoring and supervision of children) were significantly related to the development of self-control, independent of parental efficacy. Second, the effects of school socialization on youth's levels of self-control varied according to (i.e., interacted with) levels of parental efficacy as well as conditions of neighborhood deprivation. In particular, the effect of school socialization on children's development of self-control was strongest when parental efficacy was low and when neighborhood conditions were criminogenic. These results therefore highlight the ability of social institutions—in this case, the school—to pick up the slack for instilling self-control in children when other mechanisms, such as parents and the community, break down.

Future Directions

For the continued vitality of the self-control tradition, there are a number of directions future research should take. First, future empirical work should continue to focus on the complex relationships surrounding parenting and the development of self-control in children. In particular, the literature examining the influence of structural/community characteristics on parental efficacy, although certainly important, is still in its infancy. In addition, there is still a need to systematically assess the causal mechanisms underlying the relationship between ineffective parenting and self-control in children. Specifically, some scholars have highlighted the potential for “child effects” on parenting, whereby children with early temperament and behavioral problems may be more likely to elicit problematic responses from parents (e.g., overly lenient or inconsistently harsh parenting practices; see Moffitt, 1993). Nevertheless, whether these effects exist independent of parents' levels of self-control is still unclear (see Nofziger, 2008); that is, do difficult children elicit bad parenting, or do the parents of such children simply lack self-control themselves and therefore the capacity to exert vigilant and consistent control over their children? Either way, the problem is that the comparative validity of these two explanations for the parenting–self-control relationship has yet to be assessed.

Second, it would be particularly useful for future studies to continue to assess systematically the interaction effects surrounding parenting, biological and neuropsychological deficits, and community and institutional efficacy on self-control. As such, three questions are immediately salient: (1) Is the effect of neuropsychological deficit on self-control more pronounced for children with low parental efficacy? (2) Is the effect of neuropsychological deficit on self-control more pronounced for children in environments with low community or institutional efficacy? and (3) Are child effects on parental efficacy more pronounced for parents with low self-control? Answering each of these questions would help to flesh out the complexity of the causes of self-control in critically important ways.

Finally, future studies should continue the recent work of Baumeister and colleagues regarding self-control depletion (see, e.g., Baumeister, 2002). In essence, this perspective focuses on the consequences to individuals when they exercise self-control; namely, because self-control may be a limited resource within any given person, using it in one situation may partially consume it so that it may be less available in future situations. This prospect may be particularly important for individuals with relatively high levels of self-control who reside in neighborhoods plagued by multiple criminogenic risk factors (e.g., limited opportunities for legitimate participation in the labor market; constantly having to resist cultural pressures to engage in “code of the street” behavior; see Anderson, 1999). Indeed, because such individuals will inevitably be forced to exercise their self-control on a regular basis should they want to resist the criminal opportunities and temptations surrounding them, they are most likely to be susceptible to self-control depletion. Furthermore, because replenishing one's reserves of self-control takes time and distance away from the kinds of social pressures that cause depletion in the first place, individuals residing in harsh neighborhood conditions will find it more difficult to restock their levels of self-control. If this is the case, it may be that variations in the degree to which individuals' self-control becomes depleted—not merely variations in the distribution of individuals' levels of self-control—help to explain the spatial distribution of crime across communities.

Conclusion

Along with the anomie/strain and social learning traditions, Gottfredson and Hirschi's (1990) self-control theory has emerged in the last couple of decades as one of the major criminological paradigms in the field. Although a virtual empirical consensus has been reached with regard to the *consequences* of self-control (i.e., its effect on criminal and analogous behaviors), there is considerably less agreement among criminologists concerning the *causes* of self-control. What is clear, however, is that self-control as an explanation of criminal and deviant behavior is here to stay. What remains to be seen is how diligent scholars will continue to be in integrating it with other theories and how committed the self-control purists will be in resisting such a movement.

SOCIAL CONSTRUCTION OF CRIME

STUART HENRY

San Diego State University

According to social constructionists, what counts as crime varies depending on who is defining it: “There are no purely objective definitions; all definitions are value laden and biased to some degree,” and what is defined as crime by law “is somewhat arbitrary, and represents a highly selective process” (Barak, 1998, p. 21). This social constructionist challenge to the fact of crime as defined by law is rooted in a history of critical theory.

The Concept of Social Construction

Social construction is a theoretical position that cuts across a number of disciplinary and interdisciplinary fields, including sociology, psychology, psychotherapy, women’s studies, queer studies, the history and philosophy of science, narrative philosophy, and literary theory, among others. As Stam (2001) noted, social constructionism has not only permeated many fields of study but also has become part of popular culture (for overviews, see Burr, 1995; Gergen, 1999; Potter, 1996). Advocates of social constructionism argue that the social world has an existence only, or largely, through humans’ routine interaction. By identifying some features of social life as significant, distinguishing those features from others, and acting as though they have a real, concrete existence, humans create social reality.

In its extreme form, social constructionism draws on the idealist/nominalist philosophical tradition that social reality has no independent existence outside the human

mind. Humans interpret the world and make summary representations (images in their mind) that they believe reflect an underlying reality; at issue is whether there is any independent objective existence to the reality that these representations appear to reflect. Most social constructionists, however, are not total relativists but are more moderate. They believe that some fundamental reality exists; they also believe that even social constructions, once created, have a degree of reality in that they recognize that if humans define situations as real, then they are real in their consequences. Therefore, if we categorize behavior, events, and experiences as similar, and name or label them in specific ways, they appear before us as representations of object-like realities with real effects that can be experienced positively or negatively.

Although we create the realities that shape our social world, and are impacted by the actions of those who put energy into sustaining them as realities, we are also capable of changing these realities by recognizing our role in their construction. Crime is seen as one such social reality, one that we collectively construct and, by implication, can collectively deconstruct and replace with a less harmful reality.

There are different versions of social constructionist theory, depending on the extent to which theorists attribute independence to reality existing outside of the human mind and whether this attributed reality is seen a result of personal cognitive meaning creation (*personal construct theory*) or the result of shared symbolic social processes (*social constructionist theory*). There are also differences

in regard to whether theorists believe that social reality can be changed depending on how far they believe humans can free themselves from their own social constructions.

Definition and Significance

From the social constructionist perspective, *crime* is a classification of behavior defined by individuals with the power and authority to make laws that identify some behavior as offensive and render its perpetrators subject to punishment. In Western societies, legislators and courts, enforced by state agencies, have the power and authority to define crime and administer punishment. What behavior they define as crime reflects both their own values and interests and the collective norms and values of the society, or at least the most vociferous segments of it.

The extent to which the norms and values of a society represent those of the whole society or some universal human values is questionable, because what counts as crime in different societies varies in content, with a few exceptions. However, as anthropologists Alfred Kroeber and Clyde Kluckhohn (1952) pointed out in their study of many cultures, there do seem to be some universals. Kroeber and Kluckhohn claimed that among its own in-group members, no culture could be found that accepts (a) indiscriminate lying, suggesting that all societies value honesty; (b) stealing, such that all societies value rights of property ownership; (c) violence and suffering, suggesting that all societies value peaceful coexistence; and (d) incest, such that all societies restrict sexual intercourse to nonfamilial adults.

However, what counts as acceptable or unacceptable behavior in these categories varies, not only culturally and subculturally but also historically. For example, in Western industrial societies, in spite of its enormous economic cost to victims, perpetrators of corporate and white-collar crimes were, until the late 20th century, rarely subject to punishment, because the crimes of business, and white-collar crimes in particular, were not considered “real” crimes, even though they typically produced multiple victims who each suffered economic losses of up to 100 times the cost of street offenses (the typical average robbery in the United States nets \$1,200, and the typical bank robbery loss is \$4,300, compared with the typical embezzlement, which is \$17,000, and the typical corporate crime, which ranges from \$5 million–\$300 million). Whereas a bank robber typically receives a 20- to 30-year prison sentence, a bank embezzler can receive as little as 5 years’ probation. The influence of juries in deciding whether to indict or convict a person for crime can also reflect local rather than national values, as in the case of a Texas man who shot to death burglars in his next-door neighbor’s house who was not indicted by the grand jury for homicide.

Moreover, the ability of some interest groups to mobilize mass communications to influence the values of others through moral crusades targeted toward certain behaviors, such as drug use, homosexual relations, assisted suicide, smoking in public places, and so on, can significantly affect

what kinds of behavior are defined as acceptable or criminal. This stands in comparison to the human attempt to create a moral social order in which some behavior is defined as acceptable and other behavior is defined as unacceptable or deviant, through the creation of rules that ban some behaviors and subject rule violators to sanctions. Whereas deviance is taken to be a violation of social norms, crime is seen as a violation of criminal law, and whereas deviance is behavior perceived as different and negatively evaluated as threatening and morally offensive, crime is seen as harmful—physically, economically, socially, and psychologically—resulting in victims who suffer some loss, reduction, and repression of what they were prior to the offense (Henry & Lanier, 2001; Henry & Milovanovic, 1996).

However, like the social reaction to deviance, the criminal justice reaction to crime can result in labeling effects that amplify the significance of the original law violation. This process can entrench the delinquent in a career trajectory that leads to greater rather than less involvement in the offensive behavior, not least because options to engage in nonoffensive behaviors are closed off, while attributes, qualities, and skills in relation to the law violating behavior are enhanced.

Thus, the social construction of crime, through its amplification by social reaction, can produce the real consequence of *career criminals* as the offender becomes engulfed in coping with the stigma of a criminal identity that ultimately might lead to his or her embrace of that socially constructed identity through identity transformation. No longer are these just persons who broke the law by, for example, being tempted to shoplift; instead they have become “shoplifters.” Clearly the significance of the social construction process can be that more crime, rather than less, is the outcome of the attempts to control the original offensive behavior.

The actions of moral entrepreneurs to whip up public sentiment through the mass media into what has been called a *moral panic* about certain offenses is capable of producing the appearance of “crime waves” and can demonize certain categories of people. Social constructionists have focused on the practices of criminal justice agencies and moral entrepreneurs in creating moral panics through claims about the threats posed by some groups to the population as a whole.

A consequence of the social construction of crime and the creation of moral panics is that a society’s crime rate, in particular increases in certain types of crimes, can be viewed less as a consequence of a real increase in crime and more the effect of the amplification of a problem through its public discussion in the media. Furthermore, it can reflect increased public awareness of behaviors that are then defined as problematic, resulting in more reports of crimes to the police and more arrests of alleged offenders by the police. Thus, real rises and falls in crime may reflect a combination of the following: (a) actual increases in the activity, (b) the socially constructed fear of its presence, and (c) a willingness of authorities to reclassify other activities as potential crimes. Because of crime’s socially constructed nature, real trends in crime are difficult to establish.

Historical and Theoretical Roots of Social Constructionist Theory

Husserl's Transcendental Phenomenology

The roots of social constructionism can be attributed to nominalist philosophy. Although the nominalist philosophical tradition can be traced back to the 11th century and can be found in the 18th-century philosophy of Immanuel Kant and the 19th-century philosophy of Friedrich Nietzsche, it is Edmund Husserl's 20th-century *transcendental phenomenology* that laid the foundation for social constructionist theory. Husserl combined insights from philosophy, mathematics, and early psychology. He developed a method for suspending, or "bracketing," what was taken for granted as objects in the natural attitude (a commonsense, mundane approach to the world) in order to see how these are constituted in the human consciousness. The *natural attitude* is the taken-for-granted assumption that objects have material-like qualities. Husserl's phenomenological inquiry revealed how our acting toward objects as though they are real constitutes them as real; their apparent material qualities are, in part, a result of the ways in which we act intentionally toward them as real.

Schutz's Sociological Phenomenology

Husserl's transcendental phenomenology was a major influence on the work of sociologist Alfred Schutz. In his *Phenomenology of the Social World* (1932/1967), Schutz integrated Husserl's phenomenology with Max Weber's sociology, in particular with Weber's concepts of interpretive understanding and ideal-type construction, which are generalized types of behavior. Schutz saw that in their day-to-day mundane existence in the social world, humans experience both an objective and subjective existence. Humans both take this world for granted as a reality yet also see it as shared with others intersubjectively, while also interpreting it differently, depending on their past experience. Because human action is purposive, based on human interpretation and shaped as a project by past biography and social position, a socially constructed shared experience by people having different experiences produces multiple views of social reality, which leads to a position of moral relativity.

Berger and Luckmann's Social Construction of Reality

In the 1960s, during a time when Western industrial societies were undergoing significant social and political change and when protest against establishment institutions was rampant, from anti-Vietnam war protests to civil rights and women's movement protests, a social climate emerged that resonated with the intellectual view that social structures and their institutions need not be what they had always been and that they could be changed. Peter Berger and Thomas Luckmann's (1966) classic book, *The Social Construction of Reality*, captured the historical moment of

liberation from our self-made social order by building on the insights of Schutz. In this work, they showed that although society and its institutions appear to be real, having an independent and object-like existence, its reality is the outcome of a series of social processes through which humans interactively create institutionalized social phenomena but in the process lose sight of the fact that they created those phenomena. The resultant reification leaves the created social world appearing through types and patterns of behavior as an object-like entity, acting outside and independent of the humans who created it. Berger and Luckmann said that reification involves three interrelated processes: (1) externalization, (2) objectification, and (3) internalization. *Externalization* occurs through communication whereby people create categories that define and classify the events that they experience, eventually becoming patterns that are institutionalized, formalized, and codified to stand objectified apart from those who created them, who then develop "recipe knowledge" about them and how to relate to them. The process of *objectification* and explaining the existence of these object-like social entities serves to further legitimate their independent existence. The process of *internalization* occurs when knowledge about these social institutions and structures is communicated back to members of society, who embody it as part of their knowledge of social reality. Not only do humans lose sight of their role in the creation of social reality but, importantly, they also lose sight of their ability to change the world.

Garfinkel's Ethnomethodology

Harold Garfinkel's (1967) *Studies in Ethnomethodology* contributed to the development of social constructionist thinking in that, like Berger and Luckmann, Garfinkel and colleagues, such as Harvey Sacks, David Sudnow, Don Zimmerman, and Melvin Pollner, focused on how social order, social institutions, and social structure emerged from shared mundane interactions among ordinary people in their everyday lives. In defining their world and acting toward its boundaries through routine practices of interpretation, people create and negotiate categories of behavior that are deemed acceptable and categories that are unacceptable or deviant. Exploring the ways or the methods, rather than the shared meaning, by which this everyday interpretive process produces realities is the contribution made by ethnomethodology. For ethnomethodologists it is the routine practices (called *methods*) that people use to classify other people as deviants or offenders that are important in considering what is and what becomes a crime, rather than the content of the activities of people whose behavior is classified as deviant or criminal.

In studying humans in the process of coconstructing their world through conversation, language, making distinctions, and taken-for-granted assumptions, ethnomethodologists are engaged in a form of radical social constructionism (discussed further in a subsequent section of this chapter), although some scholars maintain

that the two are theoretically different (Bogen & Lynch, 1993). It is important to note that ethnomethodologists do not assume the constructions that they study exist independently of the discourse used by humans interacting; neither do they exclude their own analysis from the constitutive process.

The Social Interactionism of Mead and Blumer

Whereas ethnomethodologists were concerned with the ways of interpretation was accomplished through routine practices, Herbert Blumer, a student of social psychologist George Herbert Mead and influenced by pragmatic philosopher John Dewey's ideas about human's interaction with the environment, had been working on developing an interactionist perspective. His *Symbolic Interactionism* (1969) demonstrated that, instead of being fixed to objective roles, statuses, and structures in an interrelated system, as functionalist theorists had argued, social meaning was created through interaction and subjective interpretation with others. Mead, in his 1934 work *Mind, Self and Society*, showed that human identity was the outcome of both people's own emergent sense of self, derived from their individualized self-concept he called the *I*, and an internalized sense of the social self he called the *me*, which was derived from generalized views that others held of them that they perceived through "taking the role of the other." Blumer (1969) argued that people act toward others and the world around them on the basis of the meaning that they attributed to people, events, and structures. The meanings were not fixed but negotiated through a social process of symbolic communication both with one's self and with others, during which items were named or labeled.

From the interactionist perspective, crime is defined as a social event, involving many players, actors, and agencies. Thus, crimes can be characterized the following way:

[Crimes] involve not only the actions of individual offenders, but the actions of other persons as well. In particular, they involve the actions of such persons as victims, bystanders and witnesses, law enforcement officers, and members of political society at large. A crime, from this perspective, is a particular set of interactions among offender(s), crime target(s), agent(s) of social control and society. (Gould, Kleck, & Gertz, 1992, p. 4)

Labeling Perspective in the Sociology of Deviance

During this same period, there emerged a perspective on deviance, later applied to crime, that drew on these concepts of the social process of meaning construction through interaction and the routine ways these were accomplished. The fundamental idea was that what became designated as crime and deviance was, as Howard Becker (1963) argued, not a quality of an act a person commits but a quality of the reaction of the audience who interprets it as deviant or not. In other words, deviance was not just the result of actions by a

human actor; it depended on the audience, who signified a behavior as an act of importance and judged the act positively or negatively, labeling it good or bad. Labeling theorists argued that whether an issue becomes a public harm and/or ultimately a crime depends on a group's ability to turn private concerns into public issues or their skills at moral entrepreneurship (Becker, 1963). Creating a public harm from a private issue involves identifying and signifying offensive behavior and then attempting to influence legislators to ban it officially. Becker argued that behavior that is unacceptable in society depends on what people first label unacceptable and whether they can successfully apply the label to those designated as offenders. For example, prior to the 1930s, smoking marijuana in the United States was generally acceptable. Intensive government agency efforts, in particular by the federal Bureau of Narcotics, demonized marijuana smokers as "dope fiends," a campaign that culminated in the passage of the Marihuana Tax Act of 1937. As a result, marijuana smoking was labeled unacceptable and illegal, and those who engaged in it were stigmatized as outsiders.

Edwin Lemert (1967) made a distinction between *primary deviance* and *secondary deviance*, arguing that many people engage in minor rule violations, but only some of those people are selected to be labeled as "problems." When this occurs repeatedly, people may internalize the definitions that others have of them and undergo an identity transformation, coming to view themselves as deviants. Lemert and others, such as Erving Goffman (1963), argued that the result of this labeling could be secondary deviance, such that people who were stigmatized by the original label now act deviant because this is part of their deviant identity.

In this sense then, deviance—and, ultimately, crime—is a social construction, first because of the original process of labeling people and second as a result of the amplification of those people's deviant behavior and the interactive effects of others' actions toward them. People become deviant or criminal as a result of the iterative process between their own actions and the reactions of others to them.

Core Features of Social Constructionism

As precursors to social constructionist thought, the ideas discussed in the preceding sections formed into a theoretical perspective that some consider transcendent as a perspective across disciplines, in particular of sociology, psychology, psychotherapy, and feminism. Ten core elements have been identified as being more or less shared by scholars who take a social constructionist perspective (Henry, 2007):

1. Because of the way it is negotiated and created, "truth" about the social world or social categories in it, such as crime, should be challenged and seen as "truth claims" rather than as having any real or concrete status. Concepts such as what the real crime rate is, trends in crime, and who commits crime and why are claims about the truth rather than facts about reality.

2. Collective claims by groups about understanding social phenomena in the same ways, such as common views about what counts as crime or justice, should not be seen as evidence of an underlying reality; for example, if terrorism is a crime, then why do many nations think that U.S. foreign policy displays elements of terrorism? Does that mean that U.S. foreign policy is criminal?
3. The use of labels to classify social phenomena such as murder, theft, robbery, and rape need not reflect an underlying reality, even though the outcomes of these actions can be harmful to the victims; rape may be more an act of violence than a sex act, and food poisoning caused by systemically unhygienic restaurants may be more an act of robbery than a street mugging is.
4. What counts as reality—say, of crime, harm, and consequences—may be different across time, space, and cultures. Some examples include smoking, cocaine distribution, and environmental pollution over time and in different cultures.
5. Because of the process involved in its production, neither experts nor nonexperts have a privileged claim to reveal the truth about social phenomena such as crime; for example, the identification of a suicide or homicide depends on circumstantial evidence that coroners may know less well than relatives.
6. All knowledge is the result of social processes that are based on interaction and shared subjective meaning attached to a situation that are negotiated by the participants. These participants include, for example, robbers and their victims, as well as criminologists and their students.
7. Meaning is produced in an ongoing fashion and gains significance from the people who are attributing qualities to acts and events, as well as from the occasions when it is produced, performed, or acted toward. For example, occasional drug users may become “junkies” not through their use of drugs alone but by the way that others act toward them, label them, and limit them from normal behavior.
8. People who produce knowledge, such as criminologists, government statisticians, and professional practitioners, are no less subject to critique, and their claims are no more privileged than those of others.
9. Knowledge production about social phenomena such as crime is a political process, shaped by concentrated interests that are seeking a social or political outcome; consider, for example, claims for example that abortion is murder, homosexuality is a sin, and consumer fraud is a simply a sharp business practice.
10. Knowledge and meaning about social phenomena such as crime are not fixed but multiple, variable, and changeable through reconstructing the language and symbolic process and by altering the discursive methods that accomplish it.

Types of Social Constructionism

Although it is possible to identify the core themes that social constructionists share, there are a variety of different approaches to constructionism depending on the extent to

which advocates accept or reject realism as well as the extent to which they subject their own analysis to a constructivist critique. Gergen (1994), in *Toward Transformation in Social Knowledge*, distinguished between the psychological version of constructionism rooted in Kelly’s (1955) personal construct theory, which is concerned with how individuals cognitively construct their world by making sense of their own experiences of their environment, and the other view of social constructionism, which is rooted in the sociological interactionist–phenomenological tradition of the shared construction of meaning shaped by situational and social context, culture, and history. It is this second, social constructionist approach that has been adopted by scholars who examine crime and deviance. Within social constructionism there are three major positions: (1) radical, (2) contextual, and (3) postmodernist.

Radical Constructionists

Social constructionists such as Woolgar and Pawluch (1985), who completely reject the idea of an objective reality, are known variously as “extreme,” “radical,” “strict,” “vulgar,” or “strong” social constructionists. They see everything as socially constructed and reject the existence of an independent objective reality. Such perceived reality is seen as nothing more than the agreed-on assumptions of the specialized community that created the assumptions. Advocates of the radical version of social construction also reflexively consider their own theory as a social construction. They believe that people observe the world from different communities and make “truth claims” about constructions of the world but are not able to objectively verify the existence of the reality they perceive.

Radical constructionists also differ among themselves, with some seeing knowledge constituted by an individual’s mental process as being closed to outside influence. Such radical individual constructionists see the world as composed of collections of individual worldviews, or *multiverses*. Other radical constructionists see the world as coconstructed or coproduced, whereby the social interaction of human agents through discourse—talking, language, gestures, and other communications—coproduces shared meaning about the world. This shared meaning depends not on qualities of the individual mind but on continual construction and reconstruction in the company of others, or *recursivity*. As a result, there is a relationship between the human agent and the social world such that each constitutes and is constituted by the other (Henry & Milovanovic, 1996).

Contextual Constructionists

In contrast, some scholars, such as Spector and Kitsuse (1977/1987) and Best (1993), take what is called a “contextual,” “minimalist,” “moderate,” or “weak” view of social constructionism, believing that some underlying reality exists and that not everything is a social construction. They believe that by selecting from, interpreting, and classifying

this underlying reality, humans build social constructions that have different appearances depending on the social and cultural context. Contextual constructionists accuse radical constructionists of relativism and nihilism (Best, 1989) and, according to Best (1993), the radicals misunderstand the task of analysis, which is to locate social constructions in real cultural–structural contexts; to avoid being exclusively reflexive; and to focus on the substance of issues, evaluating false claims, and even creating new claims. However, they also acknowledge that any underlying qualities that exist do not define an event, person, or action; instead, drawing on the symbolic interactionist tradition, they argue that humans do this through a social process of definition, based on what is relevant to their purposes, shaped by their past biographical positioning, in particular by social and cultural matrices. From these social contexts humans come to agree that some categorizations are more valid than others. In other words, constructions are meaningful only when they are placed in a particular social and situational context, one that specifies the criteria of definition, relevance, and classification. As a result, the concern of contextual constructionists is to understand social problems such as crime and deviance:

[How they] are generated, sustained, taken seriously, and acted upon; and how certain claims of seriousness are advanced by specific agents and reacted to, or ignored, by different audiences. Their argument is that *by themselves* [italics added], conditions do not constitute social problems; what *makes* them social problems is how they are defined and reacted to by various segments of society. (Goode, 1997, pp. 60–61)

In contextual constructionists' opinion, to make changes for the better, people need to examine the generation and sustenance of social phenomena such as crime, describing how these phenomena are defined, defended, and reacted to. Those who take the contextual position are able to make judgments about which approach is better able to discern the nature of the construction process, how far it distorts any underlying reality, the extent of the discrepancies between objective reality and subjective experience, how realities can appear to exist and be sustained, and how changes may be made in the process to produce less harmful constructions.

Although this difference between radical and contextual constructionists is important insofar as it allows contextualists to use empirical evidence to support their claims that others are making fallacious claims (thus privileging their method of claims-making), commentators have argued that there is neither one constructionism nor many, but a cluster of core themes (as identified earlier) engaged in differently depending on the authors' aims and intent. In other words, social constructionism is itself seen as a politically framed claims-making process.

Postmodern Constructionists

In both the sociological and psychological literature, social constructionism resonates with postmodernism, discourse

analysis, and narrative theory, in particular with the affirmative or reconstructive offshoots of postmodernism, such as constitutive theory in criminology with its emphasis on “replacement discourse” (Henry & Milovanovic, 1996).

Postmodernism involves a process of deconstruction of the truth claims of others, which is designed to expose their assumptions and their arbitrariness to prevent closure and certainty. It challenges all power and authority that is based on claims to superior or privileged knowledge. The deconstructive critique is designed to resurrect and celebrate silenced voices of the marginalized to reveal the presence of multiple realities, voices, and worlds as part of a multiplicity of resistances to the hegemony of others' claims to truth.

Affirmative postmodernism is based on the assumptions of social constructionism in that reconstruction is also possible through replacement discourse (Henry & Milovanovic, 1996). Such postmodernist constructionism believes that viewing a socially constructed world through deconstruction affords the possibility of reconstructing that world. Interestingly, this perspective has developed in applied disciplines such as psychotherapy (Parry & Doan, 1994; Rosen & Kuehlwein, 1996) and criminology (Henry & Milovanovic, 1996, 1999), where some form of intervention has been deemed necessary to transform the present harmful social constructions. Indeed, in criminology, Henry and Milovanovic's (1996, 1999) *constitutive theory* seeks to deconstruct harmful discourses of domination through the reconstructive process of *replacement discourse*, not least by actively engaging the mass media's construction of what constitutes crime and harm and what counts as the criminal justice system's response.

Postmodernist constructionism emphasizes contingency rather than certainty (Butler, 1992), and it takes into account the reflexivity issue raised by ethnomethodology. As Kegan (1994) wrote, what emerges is “a theory that is mindful of the tendency of any intellectual system to reify itself” and instead “to assume its incompleteness and to seek out contradiction by which to nourish the ongoing process of its reconstruction” (pp. 329–330). For Rosen (1996), “Reconstructive postmodernism goes beyond the differentiation of the anti-modernists' stance toward the reintegration of modernism into a transformative way of knowing” (p. 42). Thus, postmodernist constructionism is a humanistic form of social science that seeks not only to reflexively understand the way humans constitute their world and are constituted by it but also to use that knowledge to help them transform it into a better place.

Crime and Deviance as Social Constructions: The Importance of Claims-Making

From the social constructionist perspective, criminal behavior is a joint human enterprise between actors and audiences.

Crime and deviance are created by human agents making distinctions, perceiving differences, engaging in behaviors, interpreting their effects, and passing judgments about the desirability or unacceptability of the behaviors or people labeled as criminal, as though those behaviors and people possessed object-like qualities. Since Spector and Kitsuse's (1977/1987) original examination of the social construction of social problems, social constructionists have tended to examine the agencies involved in the claims-making process that produces the panic rather than individuals designated as deviant or their behavior.

Most constructionist work focuses on how people in authoritative positions create moral panics around the perceived fear of certain designated behaviors, regardless of whether these behaviors exist and whether there were persons actually engaged in them. Pavarini (1994) pointed out that what becomes defined as crime depends on the power to define and the power to resist definitions. This in turn depends on who has access to the media and how skilled moral entrepreneurs are at using such access to their advantage (Pfuhl & Henry, 1993).

Crime as Moral Panic

The original concept of moral panic was used by British sociologist Stanley Cohen (1972) in his book *Folk Devils and Moral Panics*. Cohen described the demonization through the mass media around the 1960s "mods" and "rockers" teenage rebel groups whose behavior threatened valued British cultural norms. In *Moral Panics: The Social Construction of Deviance*, Erich Goode and Norman Ben-Yehuda (1994) argued that moral panics are societal reactions to perceived threat characterized by (a) volatility seen in their sudden appearance and rapid spread among large sections of the population through the mass media and other means of communications, followed by a rapid decline in further instances of the problem; (b) the growth of experts who are claimed to be authorities in discerning cases of the said feared behavior; (c) an increased identification of cases of the behavior that build into a wave; (d) hostility and persecution of the accused as enemies of society; (e) measurement of society's concern through attitude surveys; (f) consensus about the seriousness of the threat; (g) disproportional fear relative to investigations of the actual harm; (h) a backlash against the persecution; and (i) exposure of the flaws in identifying the problem. An excellent illustration is found in Jeffrey Victor's study of satanic ritualistic child abuse in his book *Satanic Panic* (1993); others include Philip Jenkins's (1998) book *Moral Panic: Changing Concepts of the Child Molester in Modern America*.

Goode and Ben-Yehuda (1994) explained the social construction of crime and deviance through moral panics by one of three models. The *grassroots model* proposes that displaced anxiety from societal stress among members of a population results in a spontaneous moral panic that

scapegoats new categories of criminals and deviants. Here, control agencies reflect opinion rather than create it. The *elite domination model* holds that people in positions of power, whether government, industry, or religious leaders, are responsible for promoting moral panic as a diversion from problems whose solution would undermine their own positions of power. Finally, the *interest group conflict model* sees the creation of moral panics as the outcome of moral entrepreneurs seeking to gain greater influence over society by defining its moral domain.

Research conducted by Victor (1998), for example, pointed out that moral panics claiming crime or deviance need not be based in reality but in imaginary offenders whose existence gains credibility in the eyes of the public when authorities and those who claim expert knowledge (in particular, science or medicine) legitimize the accusations. These panics are likely to occur when bureaucratic interest, such as competing agencies, are vying for jurisdiction of authority; when methods of detection result in errors; and as Victor claimed, when there is a symbolic resonance with a perceived threat identified in a prevailing demonology—which serves as a master cognitive frame that organizes problems, gives meaning to them, explains them, and offers solutions. A key component of moral panics is the process of claims-making.

Social constructionists of crime, deviance, and social problems examine how interest groups, moral entrepreneurs, and social movements create claims about behavior. Claims-making involves four elements in a process: (1) assembling and diagnosing claims about behavior or conditions seen as morally problematic; (2) presenting to significant audiences, such as the news media, that the claims are legitimate; (3) providing a prognosis of how to address the problem to bring about a desired outcome by defining strategies, tactics, and policy; and (4) contesting counterclaims and mobilizing the support of key groups.

Crime as a Social Construction

Social constructionist views of crime reveal that there are multiple definitions, each of which suggests a different set of criteria as constituting the phenomenon.

Legal Constructions of Crime

The starting point of the social constructionist critique is to challenge the veracity of the legal definition of crime as "an intentional act or omission in violation of criminal law (statutory and case law), committed without defense or justification, and sanctioned by the state as a felony or misdemeanor" (Tappan, 1947, p. 100). Sutherland (1949) argued that existing crime categories are constructions that distort the reality of harm. He argued that a strict legal definition excludes white-collar crime. Others have pointed out that the strict legal definition of crime also ignores the

cultural and historical context of law, such as laws on gambling and prostitution that vary by state and nation.

Powerful Interests and the Construction of Crime

Conflict between groups with different and competing interests can result in different constructions of crime such that groups in positions of power criminalize others' behavior depending on whether they threaten the interests of the powerful. The result is that powerless groups are generally the victims of oppressive laws:

Crime is a definition of human conduct created by authorized agents in a politically organized society. . . . [It describes] behaviors that conflict with the interests of the segments of society that have the power to shape public policy. (Quinney, 1970, pp. 15–16)

Groups in society form around wealth, culture, prestige, status, morality, ethics, religion, ethnicity, gender, race, ideology, human rights, the right to own guns, and so on. Each group may fight to dominate others on these issues. Ethnic or cultural conflict is a good example: What is taken for granted as acceptable behavior by one subculture is defined as criminal by another, or by mainstream culture.

When the basis of power is wealth, the conflict is considered class based. Actions defined as crime are rooted in the vast differences of wealth and power associated with class divisions. Groups that acquire power through political or economic manipulation and exploitation place legal constraints on those without power. A definition of crime based on economic interests emphasizes that “crime and deviance are the inevitable consequences of fundamental contradictions within society’s economic infrastructure” (Farrell & Swigert, 1988, p. 3). Crime is defined as the activities of those who threaten the powerful. Such a view explains why serious crimes are those of street offenders, whereas those of corporate or white-collar “suite” offenders are considered less serious. Theorists who challenge the social construction of crime through laws based on powerful interests argue that *any* behavior that causes harm is crime (Reiman, 1995). Michalowski (1985) for example, argued that we should include as crime “analogous social injury,” which is harm caused by acts or conditions that are legal. For example, promoting and selling alcoholic beverages and cigarettes (described as “drug delivery systems”), although legal, produce considerable social, health, and psychological problems.

Perhaps the most dramatic call from social constructionist-oriented critics to expand the definition of crime comes from Larry Tifft and Dennis Sullivan (2001), who argued that the hierarchical structure and social arrangements of society produce harm that evades the legal definition. They believe that these acts should be criminalized, which will render criminal many contemporary legal production and

distribution activities. It may also criminalize many of the criminal justice system’s response to crime, because these also produce additional harms.

Conclusion: Evaluation of the Social Construction of Crime

In general, social constructionists have been criticized depending on how realist or nominalist their core assumptions are. Pro-realists accuse constructionists of being nihilistic and unscientific; anti-realists ridicule any attempt at science as just another truth claim that is using scientific ideology to claim legitimacy for its own political ends (Woolgar & Pawluch, 1985). Anti-realists argue that claiming to be able to observe and document the variability in claims about a condition assumes the objectivity (i.e., reality) of the condition without reflexively subjecting one’s own analysis to the same questioning. Contextual constructionists counter that a strict anti-realist reading is an illusion that cannot be transcended by developing new language and discourse, because language is embedded in society (Best, 1995). Best (1995) called for a “weak reading” of the constructionist position, pointing out (a) that it is actually useful to locate social constructions in real cultural–structural contexts; (b) it is unavoidable and not helpful to be exclusively reflexive; and (c) that focusing on theory rather than the substance of problems may undermine and paralyze the critical edge of their constructionist position, inhibit their evaluation of false claims, and even prevent their creation of new claims.

More broadly, pure or strict social constructionism has been criticized for implying that problems of crime and deviance are merely fabrications, which is protested by the individuals suffering their consequences, even though constructionists argue that there are often real consequences of acting toward constructions as though they are real. The point of constructionism is that revealing how what is taken to be real can be deconstructed enables the possibility of it being reconstructed differently through replacement discourse; when social problems, deviance, and crime are subject to a deconstructionist analysis, they can be reframed in ways that enable their reproduction to be slowed and even reversed such that they become differently and less harmfully constituted (Henry & Milovanovic, 1996). The question—indeed, the challenge—for constructionists is how to demonstrate the value of this kind of analysis in bringing about changes in objective conditions while maintaining that these conditions are only as real as we allow them to be. The value of social constructionism is that it seeks not only to understand the way humans constitute their world and are constituted by it but also to use that knowledge to help them transform the world into a more comfortable place.

SOCIAL CONTROL THEORY

CHRISTOPHER J. SCHRECK

Rochester Institute of Technology

TRAVIS HIRSCHI

University of Arizona

The *social control* approach to understanding crime is one of the three major sociological perspectives in contemporary criminology. Control theorists believe that conformity to the rules of society is produced by socialization and maintained by ties to people and institutions—to family members, friends, schools, and jobs. Put briefly, crime and delinquency result when the individual's bond to society is weak or broken. As social bonds increase in strength, the costs of crime to the individual increase as well.

The intellectual roots of social control theory reach back several centuries, but it was not until the middle of the 20th century that this theory began to generate broad interest among crime researchers. Since then, it has been among the most frequently tested in the scientific literature and has garnered substantial empirical support. Its research and policy implications have generated perhaps the most debate of any modern theory of crime. The influence of social control theory on actual crime control policy has been less impressive. Social control theories do not support expansion of the criminal justice system. They do not favor larger police forces or lengthy incarceration as crime control policies. They favor instead policies designed to establish stronger bonds between individuals and society.

The first task of the control theorist is to identify the important elements of the bond to society. The second task is to say what is meant by *society*—to locate the persons and institutions important in the control of delinquent and criminal behavior. The following list of elements of the bond—attachment, commitment, involvement, and belief—has

proved useful in explaining the logic of the theory and in summarizing relevant research. It has also provided guidelines for evaluation of delinquency prevention programs.

Attachment

Social control theory assumes that people can see the advantages of crime and are capable of inventing and executing all sorts of criminal acts on the spot—without special motivation or prior training. It assumes that the impulse to commit crime is resisted because of the costs associated with such behavior. It assumes further that a primary cost of crime is the disapproval of the people about whom the potential offender cares. To the extent that the potential offender cares about no one, he or she is free to commit the crime in question. Sociologists often explain conformity as the result of such sensitivity. Psychologists as often explain deviation as the result of insensitivity to the concerns of others. Together, they tell us that sensitivity is a continuum and that some people have more than others and some have less than others. This is the position adopted by control theorists. They focus on the extent to which people are sensitive to the opinion of others and predict that this variable will predict rates of crime and delinquency.

Sensitivity suggests feeling or emotion, and this element of the social bond indeed attempts to capture the emotions (or lack thereof) involved in conformity and deviance. The words are many: *affection, love, concern, care, and respect,*

to name only some. Social control theorists use *attachment* as an abstract summary of these concepts.

The evidence is clear that family attachments are strongly correlated with (non)delinquency. In their famous book *Unraveling Juvenile Delinquency*, Sheldon and Eleanor Glueck (1950) indicated that, according to their research, affection of the father and the mother for the child were two of the best five predictors of delinquency. They found, too, that in the other direction, the emotional ties of the child to the parent tended to be weaker among delinquents. From this, we may conclude that family attachments play a role in the socialization of the child as well as in maintaining his or her subsequent conformity to the rules of society. Researchers have reported that family attachments may account for the apparent effects of other variables. For example, the item “Do your parents know where you are (and what you are doing) when you are away from home?” has been often found to predict levels of self-reported delinquency. These correlations are of course taken as evidence of the importance of parental supervision. They are better seen as evidence of the importance of communication between parent and child. Scandinavian scholars have shown that parents know where their children are to the extent that their children inform them of their whereabouts. In other words, well-supervised children are those who supervise themselves, those who in effect take their parents with them wherever they happen to go.

Attachment to school is also a well-established predictor of delinquency. Students who report liking school and caring about the opinion of teachers are far less likely to be delinquent regardless of how delinquency is measured. Indeed, it is practically a truism that “delinquents don’t like school.” The general principle would seem to be that withdrawal of favorable sentiments toward controlling institutions neutralizes their moral force. Rebels and revolutionaries may dispute this principle, but that says nothing about the element of truth it contains (and they prove it by their actions).

Commitment

Everyone seems to understand the paraphrased song lyric that freedom is another way of saying that one has nothing left to lose. Control theory captures this idea in the concept of *commitment*, the idea that conforming behavior protects and preserves capital, whereas crime and delinquency put it at risk. The potential delinquent calculates the costs and benefits of crime. The more he or she has to lose, the greater the potential costs of the crime and the less likely it is to be committed. What does one lose or risk losing from crime? The short answer is life, liberty, and property. The long answer, attachments aside, is that it depends on one’s assets and prospects, on one’s accomplishments and aspirations.

For young people in American society, the main arena for the display of accomplishment or achievement is the school. Athletics aside, and however diverse the curriculum, the currency of this realm is academic achievement. Also, truancy aside, of the available measures of school-related activities,

grade point average appears to be the best predictor of delinquency. Good students are likely to aspire to further education and are unlikely to commit delinquent acts or to get into difficulties with the police. Grade point average accounts for the correlation between IQ test scores and delinquency. Put another way, IQ affects delinquency through its effect of grades. It has no direct effect on delinquency. This means that the ancient idea that, other things equal, intelligent people are better able to appreciate the consequences of their acts is not supported by the data; instead, the data suggest that the correspondence between achievement and prospects on one side and delinquency on the other is just what one would expect from rational actors, whatever their level of intelligence.

Involvement

In television courtrooms, one task of the prosecutor is to establish that the defendant had the opportunity to commit the crime of which he or she is accused. Crimes are events that take place at a given point in time. Conditions necessary for their accomplishment may or may not be present. Control theorists, like most other theorists, have seized on this fact and tried to incorporate the notion of opportunity into their explanation of crime. They do so through the concept of *involvement*, which is short for “involvement in conventional activities.” The idea is that people doing conventional things—working, playing games, watching sporting events or television, doing homework, engaging in hobbies, or talking to parents—are to that extent unable to commit delinquent acts, whatever their delinquent tendencies may be.

Despite its firm place in the common sense of criminology, the idea of involvement/limited opportunity has not fared well when put to the test. More than one researcher has found that adolescents with jobs are *more* rather than less likely to be delinquent. Also, counts of the hours of the day the adolescent is doing an activity that is inconsistent with delinquent acts have proved disappointing.

There are two problems with the concept of involvement. First, it is based on a misconception of the nature of crime. Most criminal acts, perhaps especially those available to adolescents, require only seconds or minutes for their completion—the pull of the trigger, a swing of the fist, a barked command, a jimmied door, a grab from a rack or showcase. This fact allows the commission of large numbers of criminal acts by a single offender in a short period of time. (It also makes ridiculous attempts to estimate the average number of offenses committed by individual offenders in an extended period of time.) Because opportunities for crimes are ubiquitous, the hope of preventing them by otherwise occupying the potential offender has proved vain.

A second problem with this concept is that it neglects the fact that opportunities for crime reside to a large extent in the eye of the beholder. Objective conditions matter, but so do the perceptions of actors. Control theory claims that people differ in the strength of their bonds to society. It therefore predicts that people who are strongly bonded are less

likely to engage in activities that provide opportunities for delinquency and are less likely to see them should they arise.

Belief

The role of *beliefs* in the causation of delinquency is a matter of considerable dispute. Some social scientists argue that they are of central importance. Others ignore them, suggesting that they are nothing more than words that reflect (and justify) past behavior but are in no way responsible for it. Control theory rejects the view that beliefs are positive causes of delinquency, that offenders are somehow living up to their beliefs when they commit delinquent acts. Control theory is, however, compatible with the view that some beliefs prevent delinquency while others allow it.

Perhaps the principal benefit of the study of beliefs is that they help us understand how the other bonds work to prevent delinquency. For example, responses to the statement “People who break the law are almost always caught and punished” are related to delinquency in the expected direction. Individuals who disagree are more likely to report delinquent acts. What can be said about the factual accuracy of this belief? Do delinquents know the truth while nondelinquents have been systematically misinformed? The answer appears to be that both delinquents and nondelinquents are correct, at least from their point of view. In the short term, “getting away with it” may well be the rule. In the long term, offenders are typically caught and, in various ways, punished. A short-term orientation reflects a lack of commitment and is therefore conducive to delinquency. A long-term orientation is indicative of commitment and prevents delinquency. All of this teaches two lessons: (1) Manipulating beliefs without changing the reality on which they are based is unlikely to reduce the level of delinquency, and (2) changing actual levels of law enforcement efficiency is unlikely to change the beliefs that allow and disallow criminal conduct.

Historical Development

The intellectual underpinnings of social control theory may be seen in the 17th-century work of Thomas Hobbes. In his famous book *Leviathan* Hobbes described a set of basic assumptions about human nature and the origins of civil society. Hobbes believed that humans naturally seek personal advantage without regard for the rights or concerns of others. In the absence of external restraints, in a state of nature, crime is a rational choice, a “war of all against all” naturally follows, and the life of everyone is “nasty, poor, brutish, and short.” Fortunately, in Hobbes’s view, a second choice presents itself to individuals capable of calculating the costs and benefits of their actions. They can continue in a state of war, or they can establish a system of laws and a government empowered to punish those who resort to force and fraud in pursuit of their private interests. Given the choice between war and peace, rational

people choose to submit to government authority in return for the safety of their persons and property.

Hobbes’s theory of crime is a *choice* theory. People consider the costs and benefits of crime and act accordingly. The important costs of crime are those exacted by the state—which has the power to deprive citizens of life, liberty, and property. The content of the criminal law is not problematic. There is consensus that the use of force and fraud for private purposes is illegitimate. Crime is real. It is not a matter of definition; it is not a social construction that may vary from time to time and place to place.

As we have seen, social control theory accepts *choice* and *consensus*. People are not forced by unusual needs or desires to commit criminal acts. Belief in the validity of the core of the criminal law is shared by everyone. Control theory nevertheless rejects Hobbes’s view (which is still a popular view among economists and political scientists) that the important costs of crime are the penalties imposed by the state. It can reject this view because of the assumption (and fact) of consensus. Everyone agrees that theft, robbery, and murder are crimes. As a result, victims and witnesses report offenses to interested parties, and their perpetrators embarrass and shame those who know them. Shame and the penalties that follow from it are, according to social control theory, major costs of crime.

Hobbes’s view of human nature does not imply that people are inherently criminal or that they prefer crime; it suggests only that self-interest underlies whatever they do. They harm others because it gives them pleasure or advantage. They steal because stealing provides goods or money. They hit or threaten to hit others because such acts may bring status, a feeling of justice, or control of their behavior. They do good things for self-interested reasons as well. They are trustworthy and helpful because being so brings such rewards as trust and gratitude. From the point of view of their motives, there is thus no difference between offenders and nonoffenders, between criminal and noncriminal acts; all reflect the same basic desires. Thus, working from the Hobbesian view of human nature, social control theories do not ask why people commit criminal acts. They ask instead why, given the plentiful opportunities for criminal acts and their obvious benefits, people do not commit more of them.

Sociology is the dominant discipline in the study of crime. Sociologists reject Hobbes’s perspective. They see human behavior as caused rather than chosen. They tend to reject the idea of consensus, preferring the idea of cultural diversity or even culture conflict. Nevertheless, in the early years of the 20th century, sociologists in the United States often talked about *social disorganization*, the breakdown of society they saw occurring in immigrant communities and the slums of large cities. The high rates of crime and delinquency in these areas were seen as symptoms of this breakdown. In disorganized areas, unemployment is high and families, schools, and neighborhoods are too weak to control the behavior of their residents. The theory of crime implicit in the concept of social disorganization is a variety of social control theory. In the absence of the usual social restraints imposed by jobs, families, schools, churches, and

neighborhoods, delinquency flourishes. In other words, delinquency is natural, as Hobbes suggested and, worse—but contrary to Hobbes—the penalties of the criminal justice system are insufficient to contain it.

By the middle of the 20th century, the concept of social disorganization was no longer fashionable. Sociological theories had come to focus primarily on the impact of social class and culture on law-violating behavior. Lower-class adolescents were said to be forced into delinquency in their efforts to realize the American Dream or they were socialized into a lower-class culture that justifies or requires delinquent behavior. As an explanatory factor, the family had fallen from favor and the school was rarely mentioned except as an important source of strain and subsequent malicious delinquency among lower-class boys.

Sociology, however, is more than a theoretical perspective that is brought to bear in efforts to explain criminal and delinquent behavior. It is also a research discipline that attempts to locate the causes and correlates of such behavior. While sociological theories of delinquency were painting one picture of delinquency, research was painting a very different picture, and sociological researchers were forced to use or invent a sociologically incorrect language to describe it.

By the mid-20th century, hundreds of studies of delinquency had been published, and the number was growing at an ever-increasing rate. With respect to its findings, perhaps the most important was the work of a Harvard University couple, Sheldon and Eleanor Glueck. Their book *Unraveling Juvenile Delinquency* (1950), discussed earlier in this chapter, is unrivaled in the scope and complexity of its results. The Gluecks compared 500 delinquent boys with 500 nondelinquent boys on a large number of carefully measured variables: family structure and relations, school attitudes and performance, physical and mental characteristics, and attitudes and behavior. The Gluecks reported that the five best predictors of delinquency were “family” variables: (1) discipline of the boy by his father, (2) supervision of the boy by his mother, (3) affection of the father (and [4], separately, the mother) for the boy, and (5) cohesiveness of the family.

The Gluecks’s research was said to be atheoretical, and they did not advertise themselves as theorists, but there could be no doubt that their findings supported social control theory. There also could be no doubt that their characterization of their findings reflected acceptance of a control theory perspective—and rejection of then-popular sociological theories. (For example, whereas popular sociological theories assumed that delinquents tend to be eager to succeed in school, the Gluecks reported that truancy and “lack of interest in school work” were from an early age one of their defining characteristics.) In one fell swoop, then, the Gluecks put control theory back on the table.

The Gluecks were not alone; other researchers were reporting results consistent with control theory and using the language of the theory to interpret them. Albert Reiss resurrected the distinction found in the social disorganization literature between personal and social controls. Walter Reckless and colleagues advanced a *containment* theory of

delinquency that was said to account for the behavior of “good” as well as “bad” boys. Jackson Toby introduced the idea of *stakes in conformity*—the costs of delinquency to people with good reputations and bright prospects—as an important factor in the control of delinquent behavior.

During the same mid-20th century period, social control theory benefited from introduction of an innovative technique of research, what came to be known as the *self-report method*. Prior to the invention of this method, researchers had been forced to rely on official measures of delinquency, basically police and court records. The new method allowed them to ask juveniles about their delinquent activities regardless of whether they had official records. It allowed researchers at the same time to ask young people about their relationships with parents, their attitudes toward school, and much else of interest to those wishing to explain delinquent behavior. Indeed, this research technique put the explanation of delinquency in a new light. For example, whereas the Gluecks stressed the affection of the parent for the child, it now became apparent—because it could be measured—that the affection of the child for the parent should be equally, if not more, important.

Relying on the terms and assumptions of the social disorganization perspective, F. Ivan Nye (1958) undertook the first major self-report study of delinquency, distinguishing between internal control and direct and indirect forms of social control. Nye’s particular focus was on the family. He showed how parents limit access of their children to opportunities for delinquency (an example of a direct control) and how adolescents refrain from delinquency out of concern that their parents might disapprove of such actions (an indirect control). He illustrated internal control with the concept of *conscience*, which acts to prevent one from committing acts that are harmful to others.

The various strands of thought and research on social control were brought together in Travis Hirschi’s *Causes of Delinquency*, published in 1969. This book reports in a study of a large sample of junior and senior high school students using self-report and official measures of delinquency. The theory guiding the study, as well as some of the study’s findings, are summarized at the beginning of this chapter. Hirschi’s study was a small part of a larger study based on ideas compatible with alternative theories of delinquency. Hirschi was therefore able to compare and contrast the predictions of social control theory with those stemming from its major competitors. These comparisons and contrasts have proved useful in providing structure to subsequent research.

Similarities and Differences Between Social Control Theories and Other Major Theories of Crime

As we have seen, the underlying assumptions of social control theory are in many respects similar to those of classical theories of crime, theories that have come down to us under such names as *deterrence theory* and *rational choice*

theory. The differences among them are often differences in emphasis. Deterrence theory claims that the key to crime control is found in the swiftness, severity, and certainty of the punishments administered by the legal system. Rational choice theory focuses on the costs and benefits of crime. Control theorists accept the importance of punishment, but they ignore the punishments of the legal system and thereby question their role in the control of crime. They do the same with benefits of crime—that is, they ignore them on the grounds that the benefits of crime are the same as the benefits of noncrime.

The assumptions of control theories contrast sharply with those of other sociological explanations of crime. Cultural deviance or social learning theories assume that there is no natural capacity for crime. In their view, all human action, whether crime or conformity, is the product of a combination of socializing influences. Peers exert influence on the individual, as does the family and, more broadly, the prevailing culture. Where the sum total of influences directs the individual in particular instances to engage in crime, then that person will do so. Where these influences are absent, crime cannot occur. The offender is thus a conformist, albeit not to the rules of the dominant society.

Strain theories (sometimes called *anomie theories*) assume that an individual is naturally inclined to conform to standard cultural values but can be pushed into crime when the social structure fails to provide legitimate opportunities to succeed. These theorists emphasize the influence of the American Dream, which produces aspirations and desires that often (all too often, scholars say) cannot be satisfied within the limits of the law. These sociological perspectives have proved popular and adaptable. They continue to provide a foundation for critiques of social control theory.

A Critical Issue

One question that social control theory has faced from its inception relates to the role of delinquent peers. Walter Reckless (1961), a prominent theorist whose work is usually associated with control theory, concluded from the Gluecks's (1950) data that "companionship is unquestionably the most telling force in male delinquency and crime" (p. 10). If this conclusion were allowed to stand unquestioned, whatever debate there might be between social control theory and social learning theory would be settled in favor of the latter. From the beginning, control theorists have questioned the meaning of the admittedly strong correlation between one's own delinquency and the delinquency of one's friends. Their major counterhypothesis was that advanced by the Gluecks, who interpreted their own data as showing that birds of a feather flock together, so to speak. In control theory terms, this argument is that weak bonds to society lead to association with delinquents and to delinquent behavior. Companionship and delinquency thus have a common cause. The limits of this argument were readily apparent. The correlation between companionship and delinquency was so strong that no combination of its

supposed causes could possibly account for it. Social learning theorists naturally saw this as evidence against social control theory and in favor of their own theory. A compromise solution was to integrate the two theories, the idea being that lack of social control frees the adolescent to be taught crime and delinquency by his or her peers.

Hirschi resisted this compromise, observing that the two theories, if combined, would contain fatal internal contradictions. Social control theories assume that crime is natural. Social learning theories assume crime must be learned. The two assumptions cannot peacefully coexist, because one assumption must necessarily negate the other. Yet the delinquent-peer effect would not go away. Its presence forced social control theorists to confront a fact seemingly in contradiction to the theory's internal logic. Attempts were then made to explain the role of delinquent peers without violating the assumptions of control theory. Perhaps peers do not teach delinquency, but they make it easier or less risky, thus increasing the temptation to crime by lowering its costs. Assaults and robberies and burglaries are, after all, facilitated by the support of others, just as they are facilitated by muscles and guns and agility.

Another tack was to question the validity of the measures of peer delinquency. If the data collection methods were faulty, then the seemingly strong evidence supporting the delinquent peers–delinquency correlation could also be faulty. Most studies of the delinquency of peers ask the respondents to describe their friends. The results, some researchers argued, could reflect the phenomenon of *projection*, whereby study respondents, apparently describing their friends, are in fact describing themselves. Dana Haynie and Wayne Osgood (2005) tested this hypothesis. They reported that standard data do contain a good quantity of projection. Using measures of delinquency collected directly from the peers in question, they found that what was once the strongest known predictor of crime turned out to have only a modest effect, an effect that could be accounted for by alternative theories of crime. This story teaches several lessons. Persistent attention to a theoretical problem may produce unexpected results. The facts that are at the root of the problem may themselves fail to survive, and the end results of criticisms of a criminological theory do not necessarily take the form imagined by its critics.

Theoretical and Research Extensions

In its social disorganization form, social control theory was what is now called a *life course theory*. The idea was straightforward: Individuals are controlled by ties to the significant people and institutions in their lives. As they move through the various stages of life, these people and institutions automatically change. Their significance and the strength of the individual's ties to them may change as well. The favorite example was the transition from the family of orientation, with parents and siblings, to the family of procreation, with a spouse and children. In principle, the transition from one family to the other could be a period of deregulation, of

relative freedom from social bonds and a consequent high rate of delinquency. In principle, successful completion of this transition was problematic. The adolescent could end up securely wrapped in the arms of job, church, community, and family, or he or she could end up in a stage of protracted adolescence, with weak and fleeting ties to the central institutions of adulthood. Adolescent delinquents could easily end up as law-abiding adults, and adolescent conformists could easily end up as late-starting adult offenders.

The social control theory described was based on data collected at one point in time. It could not therefore deal directly with questions of change and transition. It was designed, however, with the change and transition problem firmly in mind. If the connection between juvenile delinquency and adult crime depended on events that could not be foreseen, this posed no problem for the theory. It assumed that strong bonds could weaken, or break, that the people and institutions to which one was tied could change their character or cease to exist. It assumed, too, that weak bonds could strengthen, that they could be established where none previously existed. Social control theory was thus seen as the only major theory capable of dealing with variation in levels of crime and delinquency over the life course.

Readily available data suggested, however, that the facts were not so complicated. The data suggested that differences in levels of delinquency were relatively constant across individuals, that the form of the age distribution of crime was the same from one group to another. As a result, in 1983, Hirschi and his colleague Michael Gottfredson explicitly rejected the life course perspective on crime, declaring that criminality, once established in late childhood, stabilized and did not change. Put another way, they said that if a researcher ranks children on their propensity to commit criminal acts at age 8, he or she will find the same rank order when the children are 15 and any age thereafter. They concluded that no criminological theory, including social control theory, could explain the relation between age and crime.

Shortly thereafter, Robert Sampson and John Laub came into possession of the data originally collected by Sheldon and Eleanor Gluecks in the famous study described earlier. After reworking and supplementing these data, they were able to follow the Gluecks's (1950) participants into adulthood and, by so doing, restate and test the life course (or longitudinal) version of social control theory, which they called a *theory of informal social control*. Analyses reported in their book *Crime in the Making* (1993) confirm the Gluecks's findings about the correlates of delinquency and move on to a focus on stability and change in levels of delinquency during adulthood. Their analyses (and subsequent analyses based on even more extensive data) confirm the importance for delinquency involvement of such adult social bonds as income, marriage, attachment to spouse, job stability, and commitment. It should be mentioned that their analyses of full-life histories reveal a substantial decline in crime with age that their bond measures cannot explain.

Policy Implications

Current crime control policy in the United States emphasizes the value of incarceration on the one side and treatment or rehabilitation on the other. Increased rates of incarceration have been encouraged by renewed academic interest in so-called "career criminals" and by the view that crime control requires swift, certain, and severe punishment by agents of the criminal justice system. The emphasis on punishment is encouraged by politicians, the media, an influential segment of academic criminology, and of course by law enforcement officials themselves. The crime problem is a blessing to all of them, and they do not fail to take advantage of it.

Increased levels of concern and punishment automatically produce greater numbers of potential offenders, probationers, inmates, and parolees—all of whom are thought to benefit from exposure to modern treatment and rehabilitation programs. The emphasis on treatment is encouraged by the belief that it provides a humane alternative to punishment. It is also encouraged by renewed faith in its effectiveness in reducing subsequent involvement in criminal and delinquent behavior. Where it was recently believed that treatment does not work, the question of effectiveness is now answered in advance by advocacy of evidence-based programs. An emphasis on treatment is a blessing for psychologists, social workers, and social service agencies.

Support for neither of these general policies is found in social control theory. Consistent with the theory, potential offenders are not influenced by the threat of legal penalties, and their behavior is not altered by changing the certainty or severity of such penalties. Consistent with the theory, the behavior of people exposed to the criminal justice system is not affected by such exposure. The level of punishment (e.g., the length of sentence) imposed by the system does not affect the likelihood that its wards will be seen again. Put another way, the criminal justice system receives people after they have committed offenses, but it has little or no influence on their prior or subsequent behavior.

Incarceration is sometimes justified on the grounds that it reduces the crime rate by incapacitating offenders. Even if punishment and treatment do not work, the argument goes, people in prison are not committing countable crimes while they are there, though a derivation of this argument from any version of control theory is not supportable.

The idea that crime can be prevented by treating or rehabilitating offenders is contrary to the assumptions of control theory. The theory sees crime as a choice that does not reflect illness or defective judgment but the social circumstances of the actor and the logic of the situation. The renewed enthusiasm for treatment is also not justified by research. As often as not, it seems, the difference between the treatment and control groups is disappointing, or even in the wrong direction. Given the investment in various treatment strategies and the felt need to counterbalance punitive policies, the return of a skeptical view of treatment in the near future is unlikely, but better evidence that treatment works will be required to make it a serious challenge to the control theory perspective.

Crime control strategies that go by such names as *situational crime prevention*, the *routine activity approach*, and *environmental design* are perfectly compatible with control theory. All assume that crimes may be prevented by focusing on the conditions necessary for their occurrence—by reducing their benefits, by making them more hazardous or difficult. Unlike control theory, these approaches focus on one type of crime at a time—burglary, robbery, assault—but they, too, see the potential offender as acting out of choice rather than compulsion. A choosing offender may attack a lone individual but will not consider attacking a member of a group; a choosing offender may enter an unlocked door but refrain from breaking down a door that is securely locked. The beauty of these approaches is that, to the extent they are successful, they eliminate criminals by eliminating crime. Situational crime prevention theorists like to say that “opportunity makes the thief,” but a more direct statement of their position would be that “theft makes the thief.”

Social control theories typically do not provide specific positive guidance about crime control policy. Those who attack their policy implications tend to focus on the odious implications of “control,” suggesting that control theorists favor selective incapacitation and value thoughtless conformity over individual freedom. It may be partly for this reason that control theorists are reluctant to play the policy game, but it may be that the policy implications of control theory are too obvious to bear repeating. If weakened social bonds are the reason crime flourishes, the straightforward way to reduce the crime problem would be to help individuals intensify their relationships with society. How is this to be accomplished? Control theory cannot provide particularly good answers to this question anymore than strain theory can offer unusual insight about how to improve economic conditions among the poor. We do know that stakes in conformity cannot be imposed from without, that society cannot force friends on the friendless. But we know, too, that some conditions are more conducive than others to the creation and maintenance of the natural bonds that make people consider the consequences of their acts for the lives and well-being of others. With such conditions in place, the theory claims, the need for crime control policies is greatly reduced.

SOCIAL DISORGANIZATION THEORY

JEFFERY T. WALKER

University of Arkansas, Little Rock

A description of the history and current state of social disorganization theory is not a simple undertaking, not because of a lack of information but because of an abundance of it. From its beginnings in the study of urban change and in plant biology, research related to social disorganization theory has spread to many different fields. These areas of concentration range from simple spin-offs of the original studies (Bordua, 1959; Chilton, 1964; Lander, 1954), to the variety of research in environmental criminology (Brantingham & Brantingham 1981), to the growing field related to crime mapping (Chainey & Rafcliffe, 2005), to such far-reaching topics as the behavior of fighting dogs (Stewart, 1974). Given the space limitations, this chapter limits its discussion to studies closely related to the original principles of the theory.

Precursors of Social Disorganization Theory

The forerunners of social disorganization research are probably more varied than any other area of criminological thought. The ecological study of delinquency is the result of the unlikely combination of the study of change in France, plant biology, and the growth of the urban city.

The direct lineage of social disorganization research is found in the study of plant biology. Warming (1909) proposed that plants live in “communities” with varying states

of symbiosis, or natural interdependence. Communities containing plants predominantly of the same species were more in competition with nature than with each other. Communities with several different species, however, competed for limited resources more among themselves than with the environment. Warming called this relationship a *natural economy* because of the use of resources by the plants. This natural economy was expounded on by a Haeckel (1866), who used the German word *oikos*, from which economics was formed to coin the term *ecology*.

One of the first social ecological studies was conducted by Guerry in 1833. Guerry compared the crime rates in 86 departments (counties) in France from 1825 through 1830. His study showed that crime rates had marked variation in different cities in the country. Similar studies compared different regions and cities in England (Mayhew 1862/1983), different countries in the United Kingdom (Rawson, 1839), and England and European countries (Bulwer, 1836).

The relationship between a city’s central district and juvenile delinquency was first explored by Burt in 1925, who proposed that areas in London with the highest rates of delinquency were located adjacent to the central business district, and areas with the lowest rates were located near the periphery of the city.

One of the first ecological studies undertaken in the United States was conducted by Breckinridge and Abbott in 1912. They examined the geographic distribution of the homes of juvenile delinquents in Chicago. A map showing

the location of these delinquents indicated that a disproportionate number of the juveniles' homes were located in a few areas of the city.

Park and Burgess (1928) used the terminology of Haeckel, the concepts of Warming, and the research of Breckenridge and Abbot to develop what they called *human ecology*. Specifically, Park and Burgess used the concept of symbiosis to describe the phenomenon in human communities where people work together for common goals and at the same time compete for resources. They also applied Warming's concepts of dominance and succession to describe a situation in which a stronger group would disrupt the community through change and eventually reestablish order by replacing (succeeding) a previously dominant group.

Park, Burgess, and McKenzie (1969) expanded on Park and Burgess's (1928) work by observing that certain characteristics of the population tended to cluster in rings set at about 1-mile increments from the center of Chicago and that the patterns changed dramatically from one ring to the next. For example, Park et al. found a zone of manufacturing enterprises immediately surrounding the central business district of the city. Outside this factory zone was an area of very low-income housing. In the third concentric ring, the dominant residential characteristic was working-class homes. The fourth and fifth rings from the center of the city were middle- and upper-class homes. Park et al. labeled this pattern the *Burgess zonal hypothesis*.

Development of the Theory: Shaw and McKay

Shaw and McKay (1942) used the ideas of human ecology to study the association between urban ecological characteristics and juvenile delinquency. On the basis of this research they developed *social disorganization theory*. Their study of social disorganization centered around three sets of variables: (1) physical status, (2) economic status, and (3) population status.

Shaw and McKay (1942) used three variables to measure the physical status of an area: (1) population change, (2) vacant and condemned housing, and (3) proximity to industry. They proposed that areas with high delinquency rates tended to be physically deteriorated, geographically close to areas of heavy industry, and populated with highly transient residents. The primary characteristic Shaw and McKay examined was population change. They found that as population rates increased or decreased there was a corresponding increase in delinquency. They proposed that population shifts influenced delinquency because of the process of *invasion, dominance, and succession*, a term they used for disruption of the social organization of an area because members of one (typically ethnic) group moved into another group's neighborhood. The disruption in order caused a rise in crime that would get progressively worse until the invading group became the majority; then crime

rates would return to near their previous level. To analyze the relationship between proximity to industry and delinquency, Shaw and McKay mapped industrial areas and the home addresses of juvenile delinquents. Borrowing from Park and Burgess (1928), they found that surrounding the central business district was a zone of manufacturing and industry. Surrounding the industrial zone was a ring characterized by high levels of the physical, economic, and population factors they were studying and a corresponding high delinquency rate. Moving toward the outskirts of the city, they found a reduction in the prevalence of these characteristics and the rate of delinquency. The final physical characteristic Shaw and McKay analyzed was the number of vacant and condemned homes in an area. They found that there was an association between the number of vacant and condemned homes in an area and its delinquency rate.

Next, Shaw and McKay (1942) analyzed the association between the economic status of an area and its delinquency rate. They used three variables for this analysis: (1) the number of families receiving social assistance, (2) the median rental price of the area, and (3) the number of homes owned rather than rented. Shaw and McKay found that, as the number of families receiving social assistance increased, there was a corresponding rise in delinquency rates. They concluded that delinquency was higher in areas with low economic status relative to areas with higher economic status. Next, Shaw and McKay analyzed the relationship between the median rental price and delinquency. They found that delinquency rates dropped as the median rental price of the area rose. Finally, Shaw and McKay examined the relationship between the percentage of residents who owned their own homes and the delinquency rate. Their findings revealed a significant negative relationship between home ownership and delinquency. Where home ownership was low, there were high rates of delinquency. As home ownership increased, even in small increments from the lowest level, the level of delinquency dropped, being lowest in areas with the highest levels of home ownership.

In explaining the influence of economic status on delinquency, Shaw and McKay (1942) suggested that economic conditions indirectly influence delinquency rates. They asserted that affluent areas offered an atmosphere of social controls, whereas areas of low affluence produced an environment conducive to delinquency because of the diversity of the residents. This diversity influenced rates of delinquency in the area because of the disparity in social norms. In areas of low delinquency, a substantial majority of people would not tolerate abnormal behavior. In areas of high rates of delinquency, however, some of the residents condoned delinquent acts, thus offering tacit support for these behaviors. Finally, Shaw and McKay proposed that economic status influenced delinquency in the case of owning one's home in that people who could afford to own their homes had a greater stake in the neighborhood where they would be permanent residents, whereas people renting would

expend less effort to maintain the social organization or decrease the delinquency rate of the neighborhood.

The final analysis included in Shaw and McKay's (1942) study was the relationship between the population composition of an area and its rate of delinquency. Shaw and McKay found that areas with the highest delinquency rates contained higher numbers of foreign-born and black heads of household. They cautioned that this finding does not mean that nativity or ethnicity was the cause of crime. Delinquency rates in areas containing foreign-born and minority heads of households remained constant despite the total population shift to another group. Delinquency rates also remained constant in areas where the displaced population moved. Shaw and McKay concluded that the area of study, and not the nativity or ethnicity of its residents, was the factor contributing to delinquency.

On the basis of their findings, Shaw and McKay (1942) concluded that the ecological conditions existing in areas with high delinquency were contributing to a breakdown in the social order of the area, resulting in conditions conducive to delinquency. Shaw and McKay found that conventional norms existed in high-delinquency areas but that delinquency was a highly competitive way of life, such that there was advantage for some people to engage in delinquency and there were fewer consequences. This became the core of social disorganization theory. Shaw and McKay replicated their Chicago findings in at least eight other cities. Their research also spawned a wealth of other research, becoming one of the key theoretical seeds for most of the current criminological theories.

The Second Wave: Replications of Shaw and McKay

Shaw and McKay's (1942) research generated several replications spanning more than a decade. Each added to the knowledge base of ecological literature by examining the relationships first considered by Shaw and McKay in slightly different ways. None of the replications, however, drew substantially different conclusions from those in the original study.

Lander (1954) correlated 8,464 juvenile delinquents tried in the Baltimore Juvenile Court from 1939 through 1942 with demographic variables taken from the 1940 census. Specifically, Lander analyzed juvenile delinquency in terms of the median years of school completed, median monthly rent, homes with 1.51 or more persons per room, homes needing substantial repairs or having no private bath, foreign-born and non-white residents, and owner-occupied homes.

Lander's (1954) findings followed the concentric ring pattern established by Shaw and McKay (1942). Lander noted, however, that the use of 1-mile increments for the zones oversimplified the spatial distribution of delinquency because it obscured the range of delinquency rates within each zone.

Lander's (1954) findings did not support Shaw and McKay's (1942) correlation between high delinquency rates and close proximity to industry. His results indicated that the delinquency rate in census tracts with less than 50% of the area zoned for industrial purposes was lower than the city average. Lander, however, found a more pronounced relationship in Baltimore in areas zoned for commercial use. He concluded from these findings that Shaw and McKay were correct in identifying areas close to the center of the city as the highest in delinquency but that this was primarily due to ecological factors other than proximity to industry. Lander also found no support for the correlation between population change and delinquency. Lander's conclusions are not wholly contradictory to those of Shaw and McKay, however. His findings showed that the tract with the third-highest delinquency rate had a population increase of 20% and that tracts with population increases of 40% or more and decreases of 20% or more had substantially different delinquency rates than those with little or no population change. Lander found a substantial ($r = .69$) but nonsignificant relationship between delinquency and substandard housing. He added overcrowding as an additional measure of the physical status of the area and found a substantial ($r = .73$) but nonsignificant relationship between overcrowding and delinquency.

In Lander's (1954) analysis, the median rental value of housing units in Baltimore was not significantly related to delinquency. Lander reasoned that economic variables such as rental values were an unreliable predictor because they were merely indicators of where a person might live. Lander did find a significant relationship, however, between homes owned in an area and delinquency. In fact, home ownership was the most highly correlated variable in Lander's analysis.

Lander's (1954) analysis of population status followed Shaw and McKay's (1942). Zero-order correlation of the variables demonstrated that these variables were better predictors of delinquency than physical or economic variables. Although Lander's conclusions generally supported those of Shaw and McKay, there were some differences in the findings. For example, Lander found a statistically significant, inverse relationship between delinquency and number of foreign-born residents. Lander explained this by noting that many of the foreign-born Chicago residents were recent immigrants, whereas in Baltimore most of the foreign-born residents were well integrated into the community, characterized by a high degree of home ownership. Lander also found that in areas with a moderate proportion of blacks there was a high rate of delinquency. As the percentage of blacks rose above 50%, however, the rate of delinquency dropped proportionately.

Bordua (1959) attempted to replicate part of Lander's (1954) study in an effort to clarify some of the issues that had drawn criticism. Bordua's study used delinquency data from the Detroit, Michigan, juvenile court for 1948 through 1952 and census tract data from the 1950 U.S. Census.

Bordua's (1959) physical status analysis only included substandard housing and overcrowding. His findings were generally supportive of Lander's (1954) and contradictory to Shaw and McKay's (1942). Bordua found a weaker but significant relationship between overcrowding and delinquency. Also supporting Lander and counter to the findings of Shaw and McKay, Bordua found a nonsignificant relationship between substandard housing and delinquency.

Bordua's (1959) findings regarding economic status essentially supported those of Lander (1954). Bordua found the median rental value to be nonsignificant and less substantial than Lander did. Bordua also found a significant but less substantial relationship between the percentage of homes owned and delinquency. Bordua added median income to represent economic status in the analysis and found that income was not a statistically significant indicator of delinquency.

Bordua's (1959) analysis of population variables was supportive of Shaw and McKay's (1942) research but contrary to Lander's (1954). Bordua's findings revealed that foreign birth was significantly related to delinquency but that number of black heads of households was nonsignificant. On the basis of these contradictions, Bordua chose the ratio of unrelated individuals to the total number of families as an additional measure of population status. Lander found that unrelated individuals was significantly correlated with delinquency.

Chilton (1964) used juvenile court data from Indianapolis, Indiana, from 1948 through 1950 and data from the 1950 U.S. Census to compare the findings of Lander (1954) and Bordua (1959) with those in Indianapolis. The results of Chilton's analyses of the relationship between physical characteristics and delinquency essentially confirmed the findings of the other replications. Chilton's findings of the relationship between delinquency and substandard housing showed a substantial but nonsignificant correlation with delinquency. Chilton also found a substantial correlation between overcrowded conditions (more than 1.5 persons per room) and delinquency. Unlike the other two studies, though, the degree of overcrowding in Indianapolis was one of two statistically significant indicators of delinquency. Chilton's analyses of economic variables essentially confirmed those of Lander's and Bordua's studies. The relationship between median rental value and delinquency was found to be nonsignificant and similar to Lander's. Chilton's findings concerning home ownership also supported the other replications. His findings related to population characteristics tended to refute both Shaw and McKay (1942) and the other replications. Chilton found both percentage of foreign-born people and percentage of black people to not be significantly related to delinquency in Indianapolis. He concluded that ecological research can identify general conditions associated with delinquency but that differences between cities exist such that they cannot be addressed with traditional social disorganization theory.

The findings of Lander's (1954), Bordua's (1959), and Chilton's (1964) studies suggest that although the relationship between the physical characteristics of an area and delinquency may vary by city there appears to be a sustained relationship at some level. Shaw and McKay's (1942) findings concerning the relationship between economic characteristics and delinquency were supported by the replications, but not completely. Finally, Shaw and McKay's findings concerning population characteristics and delinquency were generally not supported by the replications.

The Lean Times: Social Disorganization in the 1970s and 1980s

After the replications that followed Shaw and McKay's (1942) research, social disorganization as a theory began to decline. This was primarily a result of attacks on the use of official data in crime studies and growing criticism of theoretical problems with the theory. A few studies, however, continued to follow the principles of social disorganization. The general direction of these studies followed that of Shaw and McKay, but few followed their design closely enough to be considered replications. For example, these studies examined population status through scale measurement and analysis of change in population characteristics rather than single-variable correlations. In analyzing the association between economic status and delinquency, research in this era focused on the economic status of individuals rather than the housing conditions studied by Shaw and McKay. These studies typically measured economic characteristics through educational levels and the occupational status of residents. Because of the contradictory findings of earlier research and the growing contention that foreign birth had little to do with delinquency, these studies began to look to additional measures of population status in an effort to better measure its relationship with delinquency.

Quinney (1964) obtained data from Lexington, Kentucky, in 1960 and analyzed them with *social area analysis*. Quinney's research included three dimensions: (1) economic status, (2) family status, and (3) ethnic status. Quinney's family status was the variable most closely associated with Shaw and McKay's (1942) physical status. Quinney used census data concerning women in the workforce, fertility rates, and single-structure housing. The results of his analysis showed that family status was negatively correlated with juvenile delinquency. These findings were significant even when interaction effects of economic variables were included. Quinney used two variables to examine economic status: (1) number of school grades completed and (2) number of blue-collar workers. The results showed that juvenile delinquency was negatively correlated with economic status. Quinney used the census variable race to examine ethnic status. The racial makeup of a census tract was found to be the most highly correlated with delinquency. Quinney then conducted a second analysis to determine the degree of

delinquency exhibited by each race. This analysis revealed that white delinquency rates were lowest in areas with less than 2% blacks and increased steadily as the proportion of blacks increased, peaking in the 15% to 40% black grouping. Black delinquency, however, was highest in areas with less than 2% black or more than 50% black but was lowest when the racial mix was predominantly, but not completely, white. In a third analysis, census tracts were divided into areas of high and low economic status and high and low family status. In this analysis, delinquency rates varied in relation to economic status; however, the presence of high family status always lowered the rate of delinquency.

In a partial replication of Quinney's (1964) study, and to address the criticism of using official data in social disorganization research, Johnstone (1978) used self-reported data to test social disorganization theory. In this study, Johnstone administered self-reported delinquency questionnaires to 1,124 youth aged 14 through 18 living in Chicago. Johnstone also used a modified Shevsky-Bell social area analysis using "area status measures" and "family status measures." The results of a factor analysis revealed that area-status measures had a positive but nonsignificant relationship with fighting and weapon-related crimes and a negative and nonsignificant relationship with all other delinquency measures. In regard to family status measures, lower-class status was significantly associated with fighting and weapons offenses, burglary-larceny-robbery offenses, Uniform Crime Report Index offenses, and arrests.

An enduring criticism of Shaw and McKay's (1942) research was the assumption of a stable delinquency pattern in the community rather than one experiencing change. Bursik and Webb (1982) attempted to test this hypothesis by examining data from Chicago. They used Shaw and McKay's own data and updated it to the time of their study to facilitate an examination from 1940 to 1970 in 10-year increments. Data were drawn from all male referrals to the Chicago juvenile court in the years of 1940, 1950, 1960, and 1970 and from census data for the corresponding years. A regression analysis revealed that delinquency was not associated with the indicators of change between 1940 and 1950. For the two following periods, however, this trend was reversed. Bursik and Webb also found that communities exhibiting the most rapid change were characterized by the highest increases in delinquency. The analysis showed that communities with the highest rates of population change had an average of 12 more offenses per 1,000 youth than areas with either moderate or slow change. They concluded on the basis of these findings that it was the *nature* of the change, not the *people* involved in the change, that was affecting delinquency. In explaining how their findings differed from Shaw and McKay's, Bursik and Webb concluded that the earlier study was not wrong but that it was conducted "within a specific historical context and grounded . . . in a model of ecological process that [has] changed dramatically since the publication of the 1942 monograph" (p. 36).

Four years later, Schuerman and Kobrin (1986) conducted a study similar to Bursik and Webb's (1982) with a 20-year historical analysis of Los Angeles County. This was accomplished by gathering data from the juvenile court for 1950, 1960, and 1970 and correlating them with measures of land use, population composition, socioeconomic status, and subculture.

Schuerman and Kobrin (1986) proposed that neighborhoods travel through three stages: (1) emerging areas, with very low delinquency rates; (2) transitional areas, with moderate levels of delinquency; and (3) enduring areas, which maintain high levels of delinquency for many years. They also proposed that deterioration preceded a rise in delinquency in early stages of transition (supporting Shaw and McKay, 1942) but that as the city moved to the enduring stage, rises in the delinquency rate preceded deterioration.

In analyzing the relationship between land use (physical status) and delinquency, Schuerman and Kobrin (1986) found that the number of homes owned and land use type was inversely related with delinquency. They also found high mobility levels in persons living in high-delinquency areas. A cross-lagged regression analysis revealed that physical deterioration was most highly associated with increases in delinquency in emerging areas. As the area continued to deteriorate and delinquency rose, however, the most significant factors shifted to economic characteristics. Schuerman and Kobrin argued that the speed of change rather than the change itself that resulted in a neighborhood moving from low to high crime rates.

In analyzing the influence of socioeconomic factors on delinquency, Schuerman and Kobrin (1986) examined the occupation, unemployment, education, and housing characteristics of census tracts. This analysis revealed expected results of a low number of professional and skilled workers and a low percentage of people with advanced education in high-delinquency areas. The trend among housing characteristics in Schuerman and Kobrin's study also supported the findings of Shaw and McKay (1942) and the replications. There was a general trend from owner- to renter-occupied housing and from single to multiple housing units as one moved from low-delinquency to high-delinquency areas. This supported Shaw and McKay's proposal that delinquency was positively correlated with the percentage of people renting and negatively correlated with the percentage of homes owned. There were also significant increases in the degree of overcrowding in high-delinquency areas, which supported the findings of Lander (1954), Bordua (1959), and Chilton (1964). Unlike physical status characteristics, economic variables were not a significant factor of delinquency in emerging areas of Schuerman and Kobrin's study. Socioeconomic status preceded increases in delinquency only in transitional and enduring stages.

Schuerman and Kobrin (1986) examined four population characteristics: (1) white and (2) non-white population

and (3) white and (4) non-white female participation in the labor force. In high-delinquency areas, the percentage of blacks in the population rose slightly from 1950 through 1970, while the percentage of whites decreased dramatically in the same areas. Similar trends occurred in the female labor force participation. From 1950 through 1970, the black female participation in the labor force dropped slightly in high-delinquency areas, but the white female labor force dropped substantially. These findings were even more substantial in the cross-lagged analysis. Schuerman and Kobrin concluded from this analysis that rapid change in population characteristics, along with high rates of deterioration and population turnover, were preceding and greatly influencing the rate of increase in delinquency.

Sampson and Groves (1989) tested social disorganization theory using data from a survey of 10,905 residents in 238 localities in Great Britain. Their rationale was that previous research had relied on census data that were not valid measures of community structure or crime. Sampson and Groves also argued that survey data were superior to Shaw and McKay's (1942) reliance on official crime. They also proposed that "low economic status, ethnic heterogeneity, residential mobility, and family disruption lead to community social disorganization, which in turn, increased crime and delinquency rates" (p. 775). On the basis of their analysis, Sampson and Groves concluded that social disorganization theory was supported, stating that "between-community variations in social disorganization transmit much of the effect of community structural characteristics on rates of both criminal victimization and criminal offending" (p. 774). Furthermore, they argued for expanded support for social disorganization theory in that "Shaw and McKay's model explains crime and delinquency rates in a culture other than the United States" (p. 776).

An ironic major drawback of social disorganization research has been the relative lack of theory to guide or explain the research (Bursik, 1988). Much of the research in this area has paid tribute to social disorganization in the literature review and then simply conducted analyses with little theoretical explanation for the findings. Two authors (Sampson, 1986, and Stark, 1987) attempted to advance the theory itself and to provide a better link between neighborhood-oriented research and the theoretical foundation.

Responding to criticisms that ecological research lacked an intervening factor between the variables and criminality, Sampson (1986) proposed that a breakdown in informal social controls is this link. With this premise in mind, Sampson set out to show the link among ecological characteristics, social disorganization, loss of informal social control, and delinquency. The first link he attempted to make concerned the structural density of a neighborhood. In an earlier work, Sampson (1985) proposed that increases in density reduced the ability of a neighborhood to maintain surveillance and guardianship of youth and strangers. As the number of persons in a given living area

increased, it was more difficult to know who lived in the area. When this occurred, residents were less able to recognize their neighbors or be concerned with their activities, resulting in an increased opportunity for delinquency. Sampson also proposed a link with residential mobility whereby he argued that neighborhoods with a high population turnover had a greater number of new faces, making it difficult to distinguish between new residents and strangers. Sampson proposed that economic status was related to delinquency through the attachment or social bond a person had to the neighborhood and the neighborhood's willingness to maintain informal social control. He also proposed that people who owned their own homes had a greater attachment and commitment to the neighborhood and took steps to maintain neighborhood networks and social control. He examined two-parent versus one-parent families and their relative ability to maintain informal social control. Sampson proposed that two-parent families provided increased supervision and that because of this they were aware of and intervened in predecessors of involvement in more serious delinquent activities.

Stark (1987) furthered Sampson's (1985, 1986) effort to add a theoretical framework to social disorganization research by formalizing some of the more important aspects of Shaw and McKay's (1942) findings in developing a set of 30 propositions. The primary focus of Stark's propositional framework was on Shaw and McKay's physical status variables. The factors Stark used to analyze population status were transience of population, mixed-use neighborhoods, and overcrowding. Stark (1987) proposed that "transience weakens voluntary organizations, thereby directly reducing both informal and formal sources of social control" (p. 900). Stark also sought to provide a basis for understanding how proximity to industry and mixed-use areas influenced delinquency. Stark argued that in areas where residents lived close to commercial or industrial businesses there was more opportunity to commit delinquent acts (e.g., theft) because targets were readily available and close by. In purely residential areas, however, juveniles who wanted to commit such thefts might have to travel a great distance to get to a place where such acts could be committed. Stark proposed that economic status was linked to delinquency in two ways (physical status and population status). First, he proposed that homes in poor areas were typically more crowded; therefore, there was more anonymity and less supervision of children. Stark also linked economic status to delinquency through physical status in his proposition that "poor, dense neighborhoods tend to be mixed-use neighborhoods" (p. 902). In relating population status to delinquency, Stark proposed that physically unattractive areas reduced people's commitment to their neighborhood. This proposition also supported Shaw and McKay's conclusion that physically deteriorated areas in close proximity to industry and with a highly transient population cannot maintain commitment

to the area by the residents and cannot maintain social control of delinquency.

A Resurgence: Social Disorganization Theory in the 1990s

At least within criminology and criminal justice, the focus on neighborhoods experienced a resurgence in the 1990s. This was largely based on recognition of the increasing decline of American cities, increasing crime rates, and the popularity of community policing. This renewed focus produced a great deal of research on neighborhoods. Most of the research paid homage to social disorganization theory but largely abandoned it as a theoretical basis. Some studies, however (Bursik & Grasmick, 1993; Sampson & Raudenbush, 1999; Sampson, Raudenbush, & Earls, 1997), maintained at least some of the tenets of social disorganization theory. These studies often attempted to further the understanding of neighborhoods and crime with better methodological techniques and more appropriate data.

In one of the more extensive statements of neighborhoods and crime in the 1990s, Bursik and Grasmick (1993) presented a reformulation of social disorganization theory by placing it “within a broader systemic theory of community, which emphasized how neighborhood life is shaped by the structure of formal and informal networks of association” (p. 55). Bursik and Grasmick used as a backdrop to their argument a three-level system of relationships influencing informal social control. The first level, the strength of individual relationships within a neighborhood, formed the base for the next two levels. Bursik and Grasmick argued that strong relationships among residents would result in strong neighborhood networks, which was the second level. Bursik and Grasmick argued that when neighbors know each other, they are more likely to pay attention to events that are influencing the common good of the community. The final level of relationships were those between residents and organizations external to the neighborhood, such as local government officials or the police. This was the level at which a neighborhood would be able to marshal resources to combat invasions into the neighborhood, such as unwanted organizations (e.g., a halfway house) or crime (e.g., drug dealers).

Bursik and Grasmick (1993) found that instability greatly reduced the neighborhood residents’ ability to exert social control. At the level of residents, high population turnover made it difficult to maintain ties to other residents. For example, a tenant in a public housing unit may live there for years and never form a relationship with his or her neighbors. Residents who do not know the children of the area were less likely to intervene when the children displayed unacceptable behavior. Instability also negatively influenced the security of the neighborhood because it reduced informal surveillance. A strong neighborhood network reduced the places crime could hide from surveillance, whereas weak

networks increased the ability of crime to occur in the open without being detected.

A large part of research related to social disorganization in the 1990s began to fragment and examine only portions of social disorganization theory. For example, Elliott et al. (1996) analyzed the ethnic diversity of neighborhoods (measured by the number of different languages spoken) to examine the influence of crime based on differences in values and norms between the ethnic groups. Elliott et al. proposed that when there were a variety of languages being spoken, communication could be difficult, and consensus concerning appropriate values and behaviors for the community might not be reached. There was also considerable research related to a breakdown of the family unit. Much of this research (e.g., McNulty & Bellair, 2003) sought to examine the influence of single-family units (especially related to race) on crime. The research of P.-O. Wikström and Loeber (2000, p. 1135) indicated that youth in public housing were more likely to participate in serious offending. They argued that this could be due to the serious neighborhood disadvantage of public housing and a lack of the residents’ ability to collectively defend against crime (as stated by Bursik & Grasmick, 1993).

By the end of the 1990s, the Project on Human Development in Chicago Neighborhoods (PHDCN) began to change the nature of social disorganization research. This project used social disorganization theory as a basis for a reexamination of neighborhood crime patterns in Chicago. This was easily the most extensive research in criminology since the work of Shaw and McKay (1942) and perhaps in the history of criminology research. It spawned a wealth of publications related to social disorganization theory but that took different conceptual paths. For example, Sampson and Raudenbush (1999, p. 627) took Bursik and Grasmick’s (1993) research on the capacity of neighborhoods to control crime and introduced the concept of *collective efficacy*, defined as “cohesion among neighborhood residents combined with shared expectations for informal social control of public space” (p. 3; see also Sampson & Raudenbush 2001, p. 1).

Sampson et al. (1997) argued that collective efficacy was an intervening variable between structural conditions of neighborhoods (poverty, residential instability) and crime. They examined collective efficacy using data on 343 Chicago neighborhoods and their residents as part of PHDCN. In their analysis, Sampson et al. examined structural characteristics (disadvantage, residential stability, immigrant concentration, etc.), characteristics of residents (race, age, socioeconomic status, etc.), and collective efficacy in relation to violent crime measures. They found that collective efficacy had a statistically significant relationship to violent crime regardless of structural or individual characteristics of neighborhoods. They argued that in low-crime neighborhoods, residents used informal control to regulate the behavior of members by developing rules and collective goals for the neighborhood. For this to occur, residents must

develop relationships and trust among one another. When a neighborhood's residents had a high level of social cohesion and trust among them, informal control was easier to exert, and social disorder and crime were less likely.

In addressing the influence of collective efficacy on crime, Sampson and Raudenbush (1999) followed many of the variables used in early social disorganization research. For example, they argued that a high percentage of immigrants in an area was often associated with high levels of disadvantage. This in turn increased the disorder in the neighborhood, which would lead to high levels of crime. One of the most innovative and extensive parts of the PHDCN research involved driving down selected streets using video equipment to capture measures of physical and social disorder. Sampson and Raudenbush found that both social and physical disorder were observed in neighborhoods characterized by a diverse commercial and residential use of property. They concluded that the level of crime could be explained by collective efficacy, meaning that disadvantage, not race or the ethnic composition of a neighborhood, was responsible for high levels of crime.

Social Disorganization Theory in the 21st Century

By the turn of the 20th century, social disorganization theory had largely died out in its original form. It was replaced with (a) research paying tribute to the theory but straying from its original intent, (b) research focused on collective efficacy, and (c) research focused on neighborhood characteristics but using a different theoretical base (including the variety of research conducted under the term *environmental criminology*).

A number of studies acknowledged social disorganization but did not use the theory. These studies paid tribute to the theory by using the term *social disorganization* to describe neighborhoods, but they rarely used the tenets of the theory. These studies found that juveniles from socially disorganized neighborhoods were more likely to engage in aggressive and delinquent behaviors (P.-O. Wikström & Loeber, 2000), sexual activity at an early age (Browning, Leventhal, & Brooks-Gunn, 2004), and violence. In addition, juveniles in these neighborhoods were more likely to witness violence and develop mental health problems. P. H. Wikström and Sampson (2003) argued that the development of antisocial and delinquent propensities among children and adolescents was influenced by community socialization and that this relationship was due to the level of collective efficacy present in the neighborhood. Neighborhoods low in collective efficacy produced children who were often unsupervised, and there was little threat of repercussions for negative behaviors.

Sampson and Raudenbush (2001) also indicated allegiance to social disorganization but strayed from its original connotation. They conceded that the ability to understand

social disorganization is crucial to fully understanding urban neighborhoods. In their research, however, social disorganization consisted primarily of visual indications of neighborhood physical deterioration. They proposed that this physical deterioration was an indication of what was happening in the neighborhood, such that "disorder triggers attributions and predictions in the minds of insiders and outsiders alike, changing the calculus of prospective homebuyers, real estate agents, insurance agents, and investors" (p. 1).

Sampson and Raudenbush (2001) proposed that neighborhood structure rather than social disorganization influenced the level of disorder. Where physical and social disorder was low, high levels of collective efficacy were usually found. They proposed, however, that disorder did not produce crime. They found no relationship between disorder and homicide, suggesting that crime and disorder were both influenced by something else. They proposed that the common underlying factor comprised the characteristics of the neighborhood and the cohesiveness and informal social control of its residents (Sampson & Raudenbush, 2001). This would feed into Sampson and others' research on collective efficacy.

Continuing the line of research of Sampson and Raudenbush (2001), Morenoff, Sampson, and Raudenbush (2001) made a connection between social disorganization and what they termed *social capital*. They viewed local communities as complex systems made up of friendships, kinships, and acquaintances. They argued these groups were tied to each other through family life and other aspects of their social lives. Morenoff et al. (2001) used *social capital* to describe the social ties between people and positions. They argued social capital increases the social organization and trust within networks, which helps maintain cooperation. They proposed that neighborhoods devoid of social capital were less able to hold common values and maintain social control. This lack of control led to an inability of the neighborhood to ward off unwanted social problems, including increases in crime. Morenoff et al. did concede that if strong expectations of social control were shared among a community, few ties were necessary among neighbors.

In one of the few articles that refocused on social disorganization, Kubrin and Weitzer (2003) stated that experimental and analytical work on the connection between crime and community characteristics has led to clarification of social disorganization theory. They argued that social disorganization theory was aided in recent research by addressing it as more of a systemic model that included both intra- and extra-neighborhood factors. They argued, however, that substantive and methodological issues remained that needed to be overcome if social disorganization theory were to continue to advance.

The substantive improvements proposed by Kubrin and Weitzer (2003) included advancements in the operationalization of key concepts and the addition of mediating variables between neighborhood structural characteristics and

crime. They argued that the primary variable that has improved the theory is collective efficacy. Kubrin and Weitzer argued that, although social control was not central to social disorganization theory, formal social control (police, code enforcement, etc.) was a critical concept in social disorganization research and should be brought into future research. Finally, Kubrin and Weitzer bemoaned the fact that the culture of the neighborhood has largely been ignored in recent research. They proposed that there should be a return to the neighborhood culture included in Shaw and McKay's (1942) original work.

Kubrin and Weitzer (2003) described recent "methodological innovation" in social disorganization theory that had helped researchers test key propositions and clarify relevant causal models. They identified these innovations as dynamic models, reciprocal effects, contextual effects, and spatial interdependence. They correctly pointed out that one of Shaw and McKay's (1942) principal findings was the changing nature of cities. They decried the research following Shaw and McKay's as dismissing urban dynamics, and they called for a return to including dynamic models of neighborhood change in social disorganization research. Kubrin and Weitzer also indicated that although the reciprocal effects of crime and community were beginning to be addressed, the inclusion of models in which community characteristics could influence crime and crime could then influence community characteristics is still not sufficient. Drawing on the current trend in multilevel modeling, Kubrin and Weitzer proposed that contextual effects addressing the connection between the neighborhood and its effect on individual outcomes should receive greater attention in social disorganization theory research. Finally, Kubrin and Weitzer argued that *spatial interdependence*, whereby spatially adjacent neighborhoods could influence one another's level of disorganization, should be more fully developed in social disorganization theory and research.

Kubrin and Weitzer (2003) concluded that more complete and more rigorous testing of social disorganization theory's propositions was possible because of methodological innovations. They conceded that although researchers continued to be challenged with the proper measurement of central concepts and methodological shortcomings, social disorganization theory could greatly increase the understanding of crime at the neighborhood level with the improvements outlined in their article.

Combining many of the developments from the previous 15 years, Warner (2007) sought to delineate the forms of social control (and collective efficacy) by examining the willingness of residents to directly intervene in a situation rather than relying on formal means of control (typically the police, but also avoidance or tolerance). Like many of the previous studies, Warner paid tribute to social disorganization theory in the introduction and literature review but did little to support the theory in the research, only including disadvantage and residential mobility as classic social

disorganization variables. Other independent variables included by Warner were social ties and faith in the police. Warner found that the relationship between neighborhood disadvantage and social control was nonlinear. She argued that this meant that both highly disadvantaged and highly advantaged people were likely to use indirect methods of control (the police) or to avoid or tolerate the situation, whereas people in the middle were more likely to take direct action. Warner stated this is in opposition to the tenets of social disorganization theory, which would hold a more linear pattern of the most disadvantaged using indirect methods and the likelihood of direct action increasing as the disadvantage of the neighborhood lessened. Warner found similar patterns for residential mobility: Mobility was significantly and positively related with the likelihood of using indirect methods of social control (police, avoidance, etc.), but it was not related to the likelihood of using direct methods. Warner found support for these results in confirming the tenets of social disorganization theory.

Overall, social disorganization theory in the first decade of the 21st century seemed to fare no better than in the last part of the 20th century. The theory still received some support from research on neighborhoods, but most of the research included only parts of the theory, a few of the variables, or simply paid tribute to the theory in the literature review and then conducted neighborhood research that was faintly consistent with the theoretical foundation of social disorganization.

Future Directions

One could argue that the future of social disorganization theory looks bleak. Although it is likely to still be considered one of the major theories, especially given a continued focus on neighborhood research, it may very well dissipate in its classic form. Other than a few articles likely to be related to dissertation work, it is likely that replications or semireplications of Shaw and McKay's (1942) work will disappear. Two directions do look promising for the vestiges of social disorganization theory, however: (1) studies using data from the PHDCN and its associated collective efficacy theory and (2) work from environmental criminology.

Life course theory and research from the PHDCN has dominated much of the theoretical work over the past 20 years. Sampson and other researchers have produced many publications detailing the intricacies of crime related to neighborhood change in Chicago. The availability of these data for other researchers and its current popularity probably means that research will be using these data for at least another decade. Furthermore, the popularity of Sampson's work on collective efficacy has probably ensured numerous publications in this area for the foreseeable future.

Beginning in the late 1970s with the work of crime prevention through environmental design (Jeffery, 1971), a new area of neighborhood research was formed. This quickly

developed into what is now termed *environmental criminology*. This line of research is typically based more in routine activities theory (among other theoretical foundations) than social disorganization theory, but the tenets of social disorganization theory can easily be found in much of this line of study. A recent development in environmental criminology may signal a larger place for social disorganization theory within environmental criminology. Walker (2007) used complex systems science in an effort to improve the ability of social disorganization theory to explain neighborhood change and crime. Walker termed this new theory *ecodynamics theory* after the various theoretical traditions on which it was based (social disorganization, human ecology, environmental criminology, and complex systems theory). A few conference papers at an annual meeting on environmental criminology gave rise to the argument that social disorganization theory may continue to be tested more in its classic form by these researchers than by others in criminology.

Conclusion

Social disorganization theory has its roots in some of the oldest research in criminological theory, dating back to the early 1800s. Studies of neighborhoods, including crime characteristics, rose almost simultaneously with the development of the field of sociology. As Park began to build the Department of Sociology at the University of Chicago, he centered on the concept of human ecology. This examination of human behavior, mostly at the neighborhood level, gave rise to Burgess's research and ultimately to the hiring of Clifford R. Shaw and Henry D. McKay, who went on to become the most influential social disorganization researchers in the first half of the 20th century.

Shaw and McKay's (1942) work resulted in the formal development of social disorganization theory as an explanation of the behavior and characteristics of neighborhoods and how changes in those characteristics could influence the level of crime. After this, social disorganization theory enjoyed a time of prominence in criminological thought, producing many replications and research through the early 1960s.

Social disorganization theory fell into disrepute in the 1970s as a result of sharp criticism of Shaw and McKay's (1942) work and because of a move away from official data concerning crime. As a consequence, not much research using social disorganization theory was conducted during this time. The research that was conducted downplayed the theory, foretelling social disorganization theory's future.

Social disorganization theory made a brief resurgence in the 1990s as the deterioration of American neighborhoods and rising crime rates produced a new interest in understanding the characteristics of neighborhoods. Even during this period, however, social disorganization theory was seldom tested in its classic form, and researchers again

downplayed the theory in relation to new methods and theory. By the end of the century, the PHDCN began to produce a new line of theory based on collective efficacy.

After the turn of the 20th century, most research paid tribute to the historical importance of social disorganization theory but did little to bring its tenets into modern research. Research on collective efficacy prevailed, as did research focusing on neighborhoods but doing little to further the theory itself.

The future of social disorganization theory appears close to its current status. A few criminologists are testing the theory close to its original configuration. Most of the research is likely to follow more along the lines of collective efficacy theory or to examine neighborhoods with only parts (or even none) of the tenets of true social disorganization theory.

SOCIAL LEARNING THEORY

RONALD L. AKERS

University of Florida

WESLEY G. JENNINGS

University of Louisville

The purpose of this chapter is to provide an overview of Akers's social learning theory with attention to its theoretical roots in Sutherland's differential association theory and the behavioral psychology of Skinner and Bandura. Empirical research testing the utility of social learning theory for explaining variation in crime or deviance is then reviewed; this is followed by a discussion of recent macrolevel applications of the theory (i.e., social structure and social learning). The chapter concludes with a brief offering of suggestions for future research and a summary of the importance of social learning theory as a general theory in the criminological literature.

Origin and Overview of Social Learning Theory

Burgess and Akers's (1966) differential association-reinforcement theory was an effort to meld Sutherland's (1947) sociological approach in his differential association theory and principles of behavioral psychology. This was the foundation for Akers's (1968, 1973; Akers, Krohn, Lanza-Kaduce, & Radosevich, 1979) further development of the theory, which he came more often to refer to as *social learning theory*. Sutherland's differential association theory is contained in nine propositions:

1. Criminal behavior is learned.
2. Criminal behavior is learned in interaction with other persons in a process of communication.
3. The principal part of the learning of criminal behavior occurs within intimate personal groups.
4. When criminal behavior is learned, the learning includes (a) techniques of committing the crime, which are sometimes very complicated, sometimes very simple, and (b) the specific direction of motives, drives, rationalizations, and attitudes.
5. The specific direction of motives and drives is learned from definitions of the legal codes as favorable or unfavorable.
6. A person becomes delinquent because of an excess of definitions favorable to violation of law over definitions unfavorable to violation of the law.
7. The process of learning criminal behavior by association with criminal and anti-criminal patterns involves all of the mechanisms that are involved in any other learning.
8. Although criminal behavior is an expression of general needs and values, it is not explained by those general needs and values, because noncriminal behavior is an expression of the same needs and values.
9. Differential association varies in frequency, duration, priority, and intensity. The most frequent, longest-running, earliest and closest influences will be most efficacious or determinant of learned behavior. (pp. 6–7)

Sutherland (1947) referred to the sixth statement as the *principle of differential association*. According to Sutherland, an individual learns two types of definitions

toward committing a particular behavior. He can either learn favorable definitions from others that would likely increase the probability that he will commit the behavior, or he can learn unfavorable definitions that would likely decrease the probability that he would engage in a particular behavior. Stated in terms of criminal involvement, when an individual learns favorable definitions toward violations of the law in excess of the definitions unfavorable to violations of the law, that individual is more likely to commit the criminal act(s).

Learning favorable versus unfavorable definitions can also be described as a process whereby individuals attempt to balance pro-criminal definitions against prosocial or conforming definitions. It is logical to assume that individuals learn favorable or pro-criminal definitions for committing crime from those involved in crime themselves (i.e., the criminals) and, in contrast, learn unfavorable definitions for committing crime from those individuals who are not involved in crime, and this assumption is supported empirically. It should be remembered, however, that it is possible for law-abiding persons to expose individuals to pro-criminal attitudes and definitions, just as it is possible for an individual to learn conforming definitions from criminals (see Cressey, 1960, p. 49). According to Sutherland's (1947) seventh principle, the theory does not merely state that being associated with criminals leads to crime or that being associated with law-abiding persons leads to conforming behavior. It is the nature, characteristics, and balance of the *differential* association that affect an individual's likelihood of violating the law. More specifically, if a person is exposed to pro-criminal definitions first (priority), and these definitions increase in frequency and strength (intensity) and persist for some time (duration), the individual is more likely to demonstrate involvement in criminal and deviant acts.

Although Sutherland's (1947) differential association theory began to accumulate a rather large amount of attention throughout the sociological and criminological literature in the years after its emergence, Burgess and Akers (1966) noted that the theory had still failed to receive considerable empirical support and had yet to be adequately modified in response to some of its shortcomings and criticisms. Some of these issues included the inconsistency both within and between studies regarding the support for differential association and a common criticism among scholars on the difficulty of operationalizing the theory's concepts. In response to these criticisms and the prior failure of differential association theorists in specifying the learning process of the theory, Burgess and Akers presented their reformulated version of the theory, that is, *differential association-reinforcement theory*.

To describe their revised version in terms of its modifications and derivations from the original theory (as exemplified in Sutherland's [1947] nine principles), Burgess and Akers (1966) offered the following seven principles that illustrate the process wherein learning takes place:

1. Criminal behavior is learned according to the principles of operant conditioning (reformulation of Sutherland's Principles 1 and 8).
2. Criminal behavior is learned both in nonsocial situations that are reinforcing or discriminative and through that social interaction in which the behavior of other persons is reinforcing or discriminative for criminal behavior (reformulation of Sutherland's Principle 2).
3. The principal part of the learning of criminal behavior occurs in those groups which comprise the individual's major source of reinforcements (reformulation of Sutherland's Principle 3).
4. The learning of criminal behavior, including specific techniques, attitudes, and avoidance procedures, is a function of the effective and available reinforcers, and the existing reinforcement contingencies (reformulation of Sutherland's Principle 4).
5. The specific class of behaviors which are learned and their frequency of occurrence are a function of the reinforcers which are effective and available, and the rules or norms by which these reinforcers are applied (reformulation of Sutherland's Principle 5).
6. Criminal behavior is a function of norms which are discriminative for criminal behavior, the learning of which takes place when such behavior is more highly reinforced than noncriminal behavior (reformulation of Sutherland's Principle 6).
7. The strength of criminal behavior is a direct function of the amount, frequency, and probability of its reinforcement (reformulation of Sutherland's Principle 7). (pp. 132–145)¹

Akers (1973, 1977, 1985, 1998) has since discussed modifications to this original serial list and has further revised the theory in response to criticisms, theoretical and empirical developments in the literature, and to ease the interpretation and explanations of the key assumptions of social learning theory, but the central tenets remain the same. It is important to note here that, contrary to how social learning is often described in the literature, social learning is not a rival or competitor of Sutherland's (1947) theory and his original propositions. Instead, it is offered as a broader theory that modifies and builds on Sutherland's theory and integrates this theoretical perspective with aspects of other scholars' principles explicated in behavioral learning theory, in particular behavioral acquisition, continuation, and cessation (see Akers, 1985, p. 41). Taken together, social learning theory is presented as a more comprehensive explanation for involvement in crime and deviance compared with Sutherland's original theory; thus, any such support that it offered for differential association theory provides support for social learning theory, and findings that support social learning theory do not negate/discredit differential association theory.

The behavioral learning aspect of Akers's social learning theory (as first proposed by Burgess and Akers, 1966) draws from the classical work of B. F. Skinner, yet, more recently, Akers (1998) commented on how his theory is more closely aligned with cognitive learning theories such as those associated with Albert Bandura (1977), among others. According to Burgess and Akers (1996) and, later, Akers (1973, 1977, 1985, 1998), the specific mechanisms by which the learning process takes place are primarily

through operant conditioning or differential reinforcement. Stated more clearly, operant behavior, or voluntary actions taken by an individual, are affected by a system of rewards and punishments. These reinforcers and punishers (described later) ultimately influence an individual's decision of whether to participate in conforming and/or non-conforming behavior.

Burgess and Akers (1966) originally considered the imitation element of the behavioral learning process (or modeling) to be subsumed under the broad umbrella of operant conditioning; that is, imitation was itself seen as simply one kind of behavior that could be shaped through successive approximations and not a separate behavioral mechanism. However, Akers later began to accept the uniqueness of the learning mechanism of imitation from operant or instrumental learning and to discuss it in terms of *observational learning* or *vicarious reinforcement*. Burgess and Akers also recognized the importance of additional behavioral components and principles of learning theory, such as classical conditioning, discriminative stimuli, schedules of reinforcement, and other mechanisms.

Considering the brief overview of social learning theory as described earlier, the central assumption and proposition of social learning theory can be best summarized in the two following statements:

The basic assumption in social learning theory is that the same learning process in a context of social structure, interaction, and situation, produces both conforming and deviant behavior. The difference lies in the direction . . . [of] the balance of influences on behavior.

The probability that persons will engage in criminal and deviant behavior is increased and the probability of their conforming to the norm is decreased when they differentially associate with others who commit criminal behavior and espouse definitions favorable to it, are relatively more exposed in-person or symbolically to salient criminal/deviant models, define it as desirable or justified in a situation discriminative for the behavior, and have received in the past and anticipate in the current or future situation relatively greater reward than punishment for the behavior. (Akers, 1998, p. 50)

It is worth emphasizing that social learning theory is a general theory in that it offers an explanation for why individuals first participate in crime and deviance, why they continue to offend, why they escalate/deescalate, why they specialize/generalize, and why they choose to desist from criminal/deviant involvement. Social learning theory also explains why individuals do not become involved in crime/deviance, instead opting to participate only in conforming behaviors. Thus, considering the generality of the theory as an explanation for an individual's participation in (or lack thereof) prosocial and pro-criminal behaviors, more attention is devoted in the following paragraphs to fleshing out the four central concepts of Akers's social learning theory that have received considerable (yet varying) amounts of attention and empirical support in the criminological literature: differential association, definitions,

differential reinforcement, and imitation (Akers, 1985, 1998; Akers et al., 1979).

Differential Association

The *differential association* component in Akers's social learning theory is one of primary importance. Although its significance cannot simply be reduced to having "bad" friends, the individuals with whom a person decides to differentially associate and interact (either directly or indirectly) play an integral role in providing the social context wherein social learning occurs. An individual's direct interaction with others who engage in certain kinds of behavior (criminal/deviant or conforming) and expose the individual to the norms, values, and attitudes supportive of these behaviors affects the decision of whether the individual opts to participate in a particular behavior.

Akers has indicated that family and friends (following Sutherland's [1947] emphasis on "intimate face-to-face" groups) are typically the primary groups that are the most salient for exposing an individual to favorable/unfavorable definitions and exhibiting conforming and/or nonconforming behaviors. For the most part, learning through differential association occurs within the family in the early childhood years and by means of the associations formed in school, leisure, recreational, and peer groups during adolescence. In contrast, during young adulthood and later in life, the spouses, work groups, and friendship groups typically assume the status of the primary group that provides the social context for learning. Secondary or reference groups can also indirectly provide the context for learning if an individual differentially associates him- or herself with the behaviors, norms, values, attitudes, and beliefs with groups of individuals, including neighbors, church leaders, schoolteachers, or even what Warr (2002) called *virtual groups*, such as the mass media, the Internet, and so on.

According to the theory, the associations that occur early (priority); last longer or occupy a disproportionate amount of one's time (duration); happen the most frequently; and involve the intimate, closest, or most important partners/peer groups (intensity) will likely exert the greatest effect on an individual's decision to participate in either conforming or nonconforming behavior. Taking these elements into consideration, the theory proposes that individuals are exposed to pro-criminal and prosocial norms, values, and definitions as well as patterns of reinforcement supportive of criminal or prosocial behavior. The more an individual is differentially associated and exposed to deviant behavior and attitudes transmitted by means of his or her primary and secondary peer groups, the greater his or her probability is for engaging in deviant or criminal behavior:

The groups with which one is in differential association provide the major social contexts in which all of the mechanisms of social learning operate. They not only expose one to definitions,

but they also present one with models to imitate and differential reinforcement (source, schedule, value, and amount) for criminal or conforming behavior. (Akers & Sellers, 2004, pp. 85–86)

Definitions

Definitions are one's own orientations and attitudes toward a given behavior. These personal as opposed to peer and other group definitions (i.e., differential association) are influenced by an individual's justifications, excuses, and attitudes that consider the commission of a particular act as being more right or wrong, good or bad, desirable or undesirable, justified or unjustified, appropriate or inappropriate. Akers considered these definitions to be expressed in two types: (1) general and (2) specific. *General beliefs* are one's personal definitions that are based on religious, moral, and other conventional values. In comparison, *specific beliefs* are personal definitions that orient an individual either toward committing or away from participating in certain criminal or deviant acts. For example, an individual may believe that it is morally wrong to assault someone and choose not to partake in or condone this sort of violence. Yet, despite his belief toward violence, this same individual may not see any moral or legal wrong in smoking a little bit of marijuana here and there.

Akers also has discussed personal definitions as comprising either conventional beliefs or positive or neutralizing beliefs. *Conventional beliefs* are definitions that are negative or unfavorable toward committing criminal and deviant acts or favorable toward committing conforming behaviors. In contrast, positive or neutralizing beliefs are those that are supportive or favorable toward crime and deviance. A *positive belief* is a definition an individual holds that committing a criminal or deviant act is morally desirable or wholly permissible. For instance, if an individual believes that it is "cool" and wholly acceptable to get high on marijuana, then this is a positive belief favorable toward smoking marijuana. Not all who hold this attitude will necessarily indulge, but those who adhere to these definitions have a much higher probability of using marijuana than those who hold to conventional or negative definitions. A *neutralizing belief* also favors the commission of a criminal or deviant act, but this type of belief is influenced by an individual's justifications or excuses for why a particular behavior is permissible. For instance, one may have an initially negative attitude toward smoking marijuana but through observation of using models and through associating with users come to accept it as not really bad, or not as harmful as using alcohol, or otherwise come to justify or excuse its use.

Akers's conceptualization of *neutralizing definitions* incorporates notions of verbalizations, techniques of neutralization, and moral disengagement that are apparent in other behavioral and criminological literatures (see Bandura, 1990; Cressey, 1953; Sykes & Matza, 1957). Examples of these neutralizing definitions (i.e., justifications, rationalizations,

etc.) include statements such as "I do not get paid enough, so I am going to take these office supplies"; "The restaurant makes enough money, so they can afford it if I want to give my friends some free drinks"; "I was under the influence of alcohol, so it is not my fault"; and "This individual deserves to get beat up because he is annoying." These types of beliefs have both a cognitive and behavioral effect on an individual's decision to engage in criminal or deviant behavior. Cognitively, these beliefs provide a readily accessible system of justifications that make an individual more likely to commit a criminal or deviant act. Behaviorally, they provide an internal discriminative stimulus that presents an individual with cues as to what kind of behavior is appropriate/justified in a particular situation. For example, if a minimum-wage employee who has been washing dishes full-time at the same restaurant for 5 years suddenly gets his or her hours reduced to part-time because the manager chose to hire another part-time dishwasher, then the long-time employee might decide to steal money from the register or steal food because she believes that she has been treated unjustly and "deserves" it.

Akers and Silverman (2004) went on to argue that some personal definitions are so intense and ingrained into an individual's learned belief system, such as the radical ideologies of militant and/or terrorists groups, that these definitions alone exert a strong effect on an individual's probability of committing a deviant or criminal act. Similarly, Anderson's (1999) "code of the street" can serve as another example of a personal definition that is likely to have a significant role in motivating an individual to participate in crime or deviance. For example, if an urban inner-city youth is walking down the street and observes another youth (who resides in the same area) flaunting nice jewelry, then the urban juvenile might feel justified in "jumping" the kid and taking his jewelry because of the code of the street or the personal belief that "might makes right." Despite these examples, Akers suggested that the majority of criminal and deviant acts are not motivated in this way; they are either weak conventional beliefs that offer little to no restraint for engaging in crime/deviance or they are positive or neutralizing beliefs that motivate an individual to commit the criminal/deviant act when faced with an opportunity or the right set of circumstances.

Differential Reinforcement

Similar to the mechanism of differential association, whereby an imbalance of norms, values, and attitudes favorable toward committing a deviant or criminal act increases the probability that an individual will engage in such behavior, an imbalance in *differential reinforcement* also increases the likelihood that an individual will commit a given behavior. Furthermore, the past, present, and future anticipated and/or experienced rewards and punishments affect the probability that an individual will participate in a behavior in the first place and whether he or she continues or refrains from the behavior in the future. The differential reinforcement

process operates in four key modes: positive reinforcement, negative reinforcement, positive punishment, and negative punishment.

Consider the following scenario. John is a quiet and shy boy who has difficulty making friends. Two of his classmates approach him on the playground and tell him that they will be his friend if he hits another boy because they do not like this particular child. John may know that hitting others is not right, but he decides to go along with their suggestion in order to gain their friendship. Immediately after he punches the boy, his classmates smile with approval and invite John to come over to their house after school to play with them. This peer approval serves as *positive reinforcement* for the assault. Positive reinforcement can also be provided when a behavior yields an increase in status, money, awards, or pleasant feelings.

Negative reinforcement can increase the likelihood that a behavior will be repeated if the act allows the individual to escape or avoid adverse or unpleasant stimuli. For example, Chris hates driving to and home from work because every day he has to drive through the same speed trap on the interstate. One day, Chris decides to come into work 1 hour early so he can in turn leave 1 hour early. Chris realizes that by coming in early and subsequently leaving early, he is able to avoid the speed trap because the officers are not posted on the interstate during his new travel times. He repeats this new travel schedule the following day, and once again he avoids the speed trap. His behavior (coming in an hour early and leaving an hour early) has now been negatively reinforced because he avoids the speed trap (i.e., the negative stimulus).

In contrast to reinforcers (positive and negative), there are positive and negative punishers that serve to increase or decrease the probability of a particular behavior being repeated. For example, Rachel has always had a designated driver when she decides to go out to the bar on Friday nights, but on one particular night she decides to drive herself to and from the local bar. On her way home, she gets pulled over for crossing the yellow line and is arrested for driving under the influence. Her decision and subsequent behavior to drink and drive resulted in a painful and unpleasant consequence: an arrest (a *positive punishment*).

This last scenario is an example of *negative punishment*. Mark's mom decides to buy him a new car but tells him not to smoke cigarettes in the car. Despite his mom's warning, Mark and his friends still decide to smoke cigarettes in the vehicle. His mom smells the odor when she chooses to drive his car to the grocery store one day and decides to take away Mark's driving privileges for 2 months for not following her rules. Mark's behavior (smoking cigarettes in the car) has now been negatively punished (removal of driving privileges).

Similar to differential association, there are modalities for differential reinforcement; more specifically, rewards that are higher in value and/or are greater in number are more likely to increase the chances that a behavior will occur and be repeated. Akers clarified that

the reinforcement process does not necessarily occur in an either-or fashion but instead operates according to a *quantitative law of effect* wherein the behaviors that occur most frequently and are highly reinforced are chosen in favor of alternative behaviors.

Imitation

Imitation is perhaps the least complex of the four dimensions of Akers's social learning theory. Imitation occurs when an individual engages in a behavior that is modeled on or follows his or her observation of another individual's behavior. An individual can observe the behavior of potential models either directly or indirectly (e.g., through the media). Furthermore, the characteristics of the models themselves, the behavior itself, and the observed consequences of the behavior all affect the probability that an individual will imitate the behavior. The process of imitation is often referred to as *vicarious reinforcement* (Bandura, 1977). Baldwin and Baldwin (1981) provided a concise summary of this process:

Observers tend to imitate modeled behavior if they like or respect the model, see the model receive reinforcement, see the model give off signs of pleasure, or are in an environment where imitating the model's performance is reinforced. . . . Inverse imitation is common when an observer does not like the model, sees the model get punished, or is in an environment where conformity is being punished. (p. 187)

Although social learning theory maintains that the process of imitation occurs throughout an individual's life, Akers has argued that imitation is most salient in the initial acquisition and performance of a novel or new behavior. Thus, an individual's decision to engage in crime or deviance after watching a violent television show for the first time or observing his friends attack another peer for the first time provides the key social context in which imitation can occur. Nevertheless, the process of imitation is still assumed to exert an effect in maintaining or desisting from a given behavior.

Testing Social Learning Theory

Although full empirical tests of all of the dimensions of Akers's social learning theory did not emerge in the literature until the late 1970s, early research, such as Sutherland's (1937) qualitative study of professional theft and Cressey's (1953) well-known research on apprehended embezzlers, provided preliminary support for differential association (e.g., also offering support for social learning). Following these seminal studies, research now spanning more than five decades has continued to demonstrate varying levels of support for the various components of social learning theory, and the evidence is rather robust (see Akers & Jensen, 2006).

There are far too many studies to make an attempt to list or discuss each individually; therefore, the following discussion is limited to noting the findings of some of the most recognizable and comprehensive tests of Akers's social learning theory performed by Akers and his associates.

Akers has tested his own theory with a number of scholars over the years across a variety of samples and on a range of behaviors from minor deviance to serious criminal behavior, and this research can best be summarized in terms of four projects: (1) the Boys Town study, (2) the Iowa study, (3) the elderly drinking study, and (4) the rape and sexual coercion study. The first of these projects, and by far the most well-known and cited, is the Boys Town study (for a review, see Akers & Jensen, 2006). This research project involved primary collection of survey data from approximately 3,000 students in Grades 7 through 12 in eight communities in the Midwest. The majority of the survey questions focused on adolescent substance use and abuse, but it was also the first survey that included questions that permitted Akers and his associates (Akers et al., 1979) to fully test the four components of social learning theory.

The results of the studies relying on the Boys Town data provided overwhelming support for Akers's social learning theory, including each of its four main sets of variables of differential association, definitions, differential reinforcement, and imitation. The multivariate results indicated that greater than half of the total variance in the frequency of drinking alcohol ($R^2 = .54$) and more than two thirds of the variance in marijuana use ($R^2 = .68$) were explained by the social learning variables. The social learning variables also affected the probability that the adolescent who began to use substances would move on to more serious involvement in drugs and alcohol. Not only did the social learning variables yield a large cumulative effect on explaining substance use, but also each of the four elements exerted a substantial independent effect on the dependent variable (with the exception of imitation). The more modest results found for the effect of imitation on substance use was not surprising considering the hypothesized interrelationships among the social learning variables. Also, imitation is expected to play a more important role in initiating use (first use) versus having a strong effect on the frequency or maintenance of use. Lanza-Kaduce, Akers, Krohn, and Radosevich (1984) also demonstrated that the social learning variables were significantly correlated with the termination of alcohol, marijuana, and hard drug use, with cessation being related to a preponderance of nonusing associations, aversive drug experiences, negative social sanctions, exposure to abstinence models, and definitions unfavorable to continued use of each of these substances.

The second research project, the Iowa study, was a 5-year longitudinal examination of smoking among junior and senior high school students in Muscatine, Iowa (for a review, see Akers & Jensen, 2006). Spear and Akers (1988) provided the initial test of social learning theory on the first wave (year) of the Iowa data in an attempt to replicate the

findings of the Boys Town study. The results of the cross-sectional analysis revealed nearly identical results among the youth in the Iowa study as was previously found in the Boys Town study. Once again, the social learning variables explained over half of the variance in self-reported smoking, and each of the social learning variables had a rather strong independent effect on the outcome (with the exception of imitation). Additional evidence provided by Akers (1998) illustrated the substantial influence of the adolescents' parents and peers on their behavior. When neither of the parents or friends smoked, there was a very high probability that the adolescent abstained from smoking, and virtually none of these youth reported being regular smokers. In contrast, when the adolescent's parents and peers smoked, more than 3 out of every 4 of these youth reported having smoked, and nearly half reported being regular smokers.

The longitudinal analysis of the Iowa data also provided support for social learning theory. Path models constructed using the first 3 years of data indicated that the direct and indirect effects of the social learning variables explained approximately 3% of the variance in predicting who would be a smoker in Year 3 if that individual had not reported being a smoker in either of the 2 prior years. Although this evidence was relatively weak, stronger results were found for the ability of the social learning variables to predict the continuation and the cessation of smoking by the third year (approximately 41% explained variance; Krohn, Skinner, Massey, & Akers, 1985). Akers and Lee (1996) also provided longitudinal support for the social learning variables' capacity to predict the frequency of smoking using the complete 5 years of data from the Iowa study and revealed some reciprocal effects for smoking behavior on the social learning variables.

The third project was a 4-year longitudinal study of the frequency of alcohol use and problem drinking among a large sample of elderly respondents in four communities in Florida and New Jersey (for a review, see Akers & Jensen, 2006). Similar to the results of the Boys Town and Iowa studies, which examined substance use among adolescents, the multivariate results in this study of elderly individuals also demonstrated significant effects for the social learning variables as predictors of the frequency of alcohol use and problem drinking. The social learning process accounted for more than 50% of the explained variance in self-reported elderly alcohol use/abuse.

The last project by Akers and his associates reviewed here is a study of rape and sexual coercion among two samples of college men (Boeringer, Shehan, & Akers, 1991). The findings in these studies also mirrored the results of the previous studies by Akers and his associates, with the social learning variables exerting moderate to strong effects on self-reported use of nonphysical coercion in sex in addition to predicting rape and rape proclivity (i.e., the readiness to rape). Although Akers and his associates have continued to test social learning theory to various degrees using dependent variables such as adolescent

alcohol and drug use (Hwang & Akers, 2003), cross-national homicide rates (Akers & Jensen, 2006), and even terrorism (Akers & Silverman, 2004), the findings from the classic studies just reviewed clearly identify the strength of the empirical status of social learning theory.

Social Structure and Social Learning: Theoretical Assumptions and Preliminary Evidence

Akers's social learning theory has explained a considerable amount of the variation in criminal and deviant behavior at the individual level (see Akers & Jensen, 2006), and Akers (1998) recently extended it to posit an explanation for the variation in crime at the macrolevel. Akers's *social structure and social learning* (SSSL) theory hypothesizes that there are social structural factors that have an indirect effect on individuals' behavior. The *indirect effect hypothesis* is guided by the assumption that the effect of these social structural factors is operating through the social learning variables (i.e., differential association, definitions, differential reinforcement, and imitation) that have a direct effect on individuals' decisions to engage in crime or deviance. Akers (1998; see also Akers & Sellers, 2004, p. 91) identified four specific domains of social structure wherein the social learning process can operate:

1. *Differential social organization* refers to the structural correlates of crime in the community or society that affect the rates of crime and delinquency, including age composition, population density, and other attributes that lean societies, communities, and other social systems "toward relatively high or relatively low crime rates" (Akers, 1998, p. 332).
2. *Differential location in the social structure* refers to sociodemographic characteristics of individuals and social groups that indicate their niches within the larger social structure. Class, gender, race and ethnicity, marital status, and age locate the positions and standing of persons and their roles, groups, or social categories in the overall social structure.
3. *Theoretically defined structural variables* refer to anomie, class oppression, social disorganization, group conflict, patriarchy, and other concepts that have been used in one or more theories to identify criminogenic conditions of societies, communities, or groups.
4. *Differential social location* refers to individuals' membership in and relationship to primary, secondary, and reference groups such as the family, friendship/peer groups, leisure groups, colleagues, and work groups.

With attention to these social structural domains, Akers contended that the differential social organization of society and community and the differential locations of individuals within the social structure (i.e., individuals' gender, race, class, religious affiliation, etc.) provide the context in which learning occurs (Akers & Sellers, 2004, p. 91). Individuals'

decisions to engage in crime/deviance are thus a function of the environment wherein the learning takes place and the individuals' exposure to deviant peers and attitudes, possession of definitions favorable to the commission of criminal or deviant acts, and interactions with deviant models. Stated in terms of a causal process, if the social learning variables mediate social structural effects on crime as hypothesized, then (a) the social structural variables should exhibit direct effects on the social learning variables; (b) the social structural variables should exert direct effects on the dependent variable; and (c) once the social learning variables are included in the model, these variables should demonstrate strong independent effects on the dependent variable, and the social structural variables should no longer exhibit direct effects on the dependent variable, or at least their direct effects should be substantially reduced.

Considering the relative novelty of Akers's proposed social structure and social learning theory, only a handful of studies thus far have attempted to examine its theoretical assumptions and/or its mediation hypothesis. However, the few preliminary studies to date have demonstrated positive findings in support of social structure and social learning for delinquency and substance use, elderly alcohol abuse, rape, violence, binge drinking by college students, and variation in cross-national homicide rates (for a review, see Akers & Jensen, 2006). Yet, despite the consistency of positive preliminary findings in support of Akers's social structure and social learning theory, there are some nonsupportive findings, and it is still too soon to make a definitive statement that social learning is the primary mediating force in the association between social structure and crime/deviance. Nevertheless, these few studies provide a suitable benchmark against which future studies testing the theory can build upon and improve.

Future Directions

The future of social learning theory lies along three paths. First, there will continue to be further and more accurate tests of social learning at the micro- or process level (i.e., at the level of differences across individuals), including measures of variables from other criminological theories, and these studies will use better measures of all of the central concepts of the theory. Having said this, it is not likely that the empirical findings will be much different from the research so far, but these future studies should continue to include more research on social learning explanations of the most serious and violent criminal behavior as well as white-collar and corporate crime.

Second, there is need for continued development and testing of the SSSL model, again using better measures. A very promising direction that this could take would follow the lead of Jensen and Akers (2003, 2006) to extend the basic social learning principles and the SSSL model "globally" to the most macrolevel. Structural theories at that level

are more apt to be valid the more they reference or incorporate the most valid principles found at the individual level, and those are social learning principles.

Third, social learning principles will continue to be applied in cognitive-behavioral (Cullen, Wright, Gendreau, & Andrews, 2003) prevention, treatment, rehabilitation, and correctional programs and otherwise provide some theoretical underpinning for social policy. Research on the application and evaluations of such programs have thus far found them to be at least moderately effective (and usually more effective than alternative programs), but there are still many unanswered questions about the feasibility and effectiveness of programs designed around social learning theory.

Future research along all of these lines is also more likely to be in the form of longitudinal studies over the life course and to be cross-cultural studies of the empirical validity of the theory in different societies. If social learning is truly a general theory, then it should have applicability to the explanation and control of crime and deviance not only in American and Western societies but also societies around the world. There have already been some cross-cultural studies supporting the social learning theory (see, e.g., Hwang & Akers, 2003; Miller, Jennings, Alvarez-Rivera, & Miller, 2008), but much more research needs to examine both how well the theory holds up in different societies and on how much variation there is in the effects of the social learning variables in different cultures.

Conclusion

The purpose of this chapter was to provide a historical overview of the theoretical development of Akers's social learning theory, review the seminal research testing the general theory, and discuss the recently proposed macro-level version of social learning theory (i.e., social structure and social learning), as well as offer suggestions of where future research may wish to proceed in order to further advance the status of the theory. What is clear from the research evidence presented in this chapter, along with a number of studies that have not been specifically mentioned or discussed in this chapter (for a review, see Akers & Jensen, 2006), is that social learning has rightfully earned its place as a general theory of crime and deviance. One theorist has referred to it (along with control and strain theories) as constituting the "core" of contemporary criminological theory (Cullen, Wright, & Blevins, 2006). The theory has been rigorously tested a number of times, not only by the theorist himself but also by other influential criminologists and sociologists; it has been widely cited in the scholarly literature and in textbooks; it is a common topic covered in a variety of undergraduate and graduate courses; and it provides a basis for sound policy and practice.

Ultimately, the task levied at any general theory of crime and deviance is that it should be able to explain

crime/deviance across crime/deviance type, time, place, culture, and context. Therefore, if past behavior is the best predictor of future behavior, then the expectation is that social learning theory will continue to demonstrate its generalizability across these various dimensions and that future tests of Akers's SSSL theory will also garner support as a macrolevel explanation of crime. Yet these outcomes are indeed open to debate. No theory can account for all variations in criminal behavior. Only through the process of continuing to subject the theory and its macrolevel version to rigorous and sound empirical tests in sociology and criminology can it be determined how much the theory can account for on its own and in comparison to other theories.

Note

1. In their reformulation of the theory, Burgess and Akers chose to omit Sutherland's ninth principle.

STRAIN THEORIES

ROBERT S. AGNEW

Emory University

S*train theories* state that certain strains or stressors increase the likelihood of crime. These strains involve the inability to achieve one's goals (e.g., monetary or status goals), the loss of positive stimuli (e.g., the death of a friend, the loss of valued possessions), or the presentation of negative stimuli (e.g., verbal and physical abuse). Individuals who experience these strains become upset, and they may turn to crime in an effort to cope. Crime may be a way to reduce or escape from strains. For example, individuals may steal the money they want or run away from the parents who abuse them. Crime may be used to seek revenge against the source of strain or related targets. For example, individuals may assault the peers who harass them. Crime also may be used to alleviate negative emotions; for example, individuals may engage in illicit drug use in an effort to make themselves feel better. Strain theories are among the dominant explanations of crime, and, as discussed in this chapter, certain strain theories have had a major impact on efforts to control crime.

This chapter describes (a) the types of strain most conducive to crime, (b) why strains increase the likelihood of crime, and (c) the factors that increase the likelihood that individuals will cope with strains through crime. All strain theories acknowledge that most individuals cope with strains in a legal manner. For example, most individuals cope with monetary problems by doing such things as cutting back on expenses, borrowing money, or working extra hours. It is therefore critical to explain why some

individuals engage in criminal coping. After presenting a basic overview of strain theories, this chapter describes how strain theories have been used to explain group differences, such as gender differences, in crime. The chapter concludes with a discussion of the policy implications of strain theories.

Types of Strain Most Conducive to Crime

Inability to Achieve Monetary Success

Merton (1938) developed the first major strain theory of crime in the 1930s. This theory was developed in the midst of the Great Depression, so it is not surprising that it focused on that type of strain involving the inability to achieve monetary success. According to Merton, everyone in the United States—regardless of class position—is encouraged to strive for monetary success. At the same time, lower-class individuals are frequently prevented from achieving such success through legal channels. In particular, the parents of lower-class children often do not equip them with the skills and attitudes necessary to do well in school. Lower-class individuals often attend inferior schools, and they often lack the funds to obtain college educations or start their own businesses. As a consequence, they more often find themselves unable to achieve their monetary goals through legal channels.

This goal blockage creates much frustration, and individuals may cope by engaging in crime, including income-generating crimes such as theft, drug selling, and prostitution. Merton (1938), however, emphasized that most individuals do not cope with this strain through crime. Some individuals simply endure this strain, others lower their desire for money, and still others turn to the pursuit of other goals. Merton provided some guidance as to why some individuals cope with crime and others do not. One key factor, for example, is whether individuals blame their inability to achieve monetary success on themselves or on others. Crime is more likely when the blame is placed on others.

Cohen (1955) and Cloward and Ohlin (1960) have applied Merton's (1938) theory to the explanation of juvenile gangs. Like Merton, they said that the major type of strain in the United States is the inability to achieve monetary success or, in the case of Cohen, the somewhat broader goal of middle-class status. However, they went on to state that juveniles sometimes cope with this strain by forming or joining delinquent groups, such as gangs. Strained juveniles may form gangs in order to better pursue illicit money-making opportunities, such as drug selling. They may form gangs in an effort to achieve the status or respect they desire. In particular, juveniles sometimes join gangs in an effort to feel important.

Other Strains Conducive to Crime

Beginning in the 1960s and 1970s, criminologists began to suggest that the inability to achieve monetary success or middle-class status was not the only important type of strain. For example, Greenberg (1977) and Elliott, Huizinga, and Ageton (1979) suggested that juveniles pursue a broad range of goals, including popularity with peers, autonomy from adults, and harmonious relations with parents. They claimed that the inability to achieve any of these goals might result in delinquency. Later, Agnew (1992) drew on the stress literature in psychology and sociology to point to still other types of strain.

According to Agnew (1992), *strain* refers to events and conditions that are disliked by individuals. These events and conditions may involve the inability to achieve one's goals. As indicated earlier in this chapter, however, strains may also involve the loss of positive stimuli and the presentation of negative stimuli. In more simplistic language, strains involve situations in which individuals (a) lose something good, (b) receive something bad, or (c) cannot get what they want. These ideas formed the basis of Agnew's *general strain theory* (GST), now the dominant version of strain theory in criminology.

Literally hundreds of specific strains fall under the three broad categories of strain listed in GST. Not all of these strains are conducive to crime, however. For example, homelessness is a type of strain that is very conducive to crime. Being placed in "time out" by one's parents for misbehaving is a type of strain that is not conducive to crime. GST states that strains are most likely to lead to

crime when they (a) are high in magnitude, (b) are perceived as unjust, (c) are associated with low social control (or with little to lose from crime), and (d) create some pressure or incentive for criminal coping (see Agnew, 2006). Homelessness is clearly conducive to crime: It is high in magnitude, often perceived as unjust, and associated with low social control (individuals who are homeless have little to lose by engaging in crime). Furthermore, being homeless creates much pressure to engage in crime, because one must often steal to meet basic needs and engage in violence to protect oneself (see Baron, 2004). Being placed in time out for misbehavior has none of these characteristics.

GST lists the strains most likely to result in crime. These include the inability to achieve monetary goals as well as a good number of other strains. In particular, the following specific strains are most likely to result in crime:

- *Parental rejection.* Parents do not express love or affection for their children, show little interest in them, and provide little support to them.
- *Harsh/excessive/unfair discipline.* Such discipline involves physical punishment, the use of humiliation and insults, screaming, and threats of injury. Also, such discipline is excessive given the nature of the infraction or when individuals are disciplined when they do not deserve it.
- *Child abuse and neglect.* This includes physical abuse; sexual abuse; emotional abuse; and the failure to provide adequate food, shelter, or medical care.
- *Negative school experiences.* These include low grades, negative relations with teachers (e.g., teachers treat the juvenile unfairly, humiliate or belittle the juvenile), and the experience of school as boring and a waste of time.
- *Abusive peer relations.* Peer abuse includes insults, gossip, threats, attempts to coerce, and physical assaults.
- *Work in "bad" jobs.* Such jobs have low pay, little prestige, few benefits, little opportunity for advancement, coercive control (e.g., threats of being fired), and unpleasant working conditions (e.g., simple, repetitive tasks; little autonomy; physically taxing work).
- *Unemployment,* especially when it is chronic and blamed on others.
- *Marital problems,* including frequent conflicts and verbal and physical abuse.
- *Criminal victimization.*
- *Discrimination* based on race/ethnicity, gender, or religion.
- *Homelessness.*
- *Failure to achieve certain goals,* including thrills/excitement, high levels of autonomy, masculine status, and monetary goals.

Research on Strains and Crime

Researchers have examined the effect of most of the preceding strains on crime. Their studies suggest that these strains do increase the likelihood of crime, with certain of

them being among the most important causes of crime (see Agnew, 2006, for an overview). For example, parental rejection, harsh discipline, criminal victimization, and homelessness have all been found to have relatively large effects on crime. The following are two examples of recent research in this area. Spano, Riveria, and Bolland (2006) found that juveniles who were violently victimized were much more likely to engage in subsequent violence. This held true even after they took account of such things as the juvenile's sex, age, prior level of violence, level of parental monitoring, and whether the juvenile belonged to a gang. Baron (2004) studied a sample of homeless street youth in a Canadian city and found that crime was much more common among youth who reported that they had been homeless for many months in the prior year. This finding was true even after a broad range of other factors were taken into account, such as age, gender, and criminal peer association.

These findings, however, test only one part of GST. GST not only asserts that certain strains increase the likelihood of crime but also describes *why* these strains increase crime. The next section focuses on this topic.

Why Strains Increase the Likelihood of Crime

Strains are said to increase the likelihood of crime for several reasons. Most notably, they lead to negative emotions such as anger, frustration, depression, and fear. These emotions create pressure for corrective action; that is, strained individuals feel bad and want to do something about it. Crime is one possible response. As indicated earlier in this chapter, crime may be a means for reducing or escaping from strains, seeking revenge against the source of strain or related targets, or alleviating negative emotions (through illicit drug use). Anger occupies a special place in GST, because it energizes individuals for action, reduces inhibitions, and creates a strong desire for revenge.

Several attempts have attempted to determine whether strains lead to negative emotions and whether these emotions, in turn, lead to crime. Most studies have focused on the emotion of anger, and they tend to find that strains increase anger and that anger explains part of the effect of strains on crime—especially violent crime (Agnew, 2006). For example, Jang and Johnson (2003) asked individuals to indicate the strains or personal problems they had experienced. Many such strains were listed, including different types of financial problems, family problems, and criminal victimizations. Jang and Johnson found that individuals who experienced more strains were more likely to report feeling angry and that this anger had a large effect on crime.

A few studies also suggest that emotions such as depression, frustration, and fear may sometimes explain the effect of strains on crime (see Agnew, 2006). Recently,

researchers have suggested that certain strains may be more likely to lead to some emotions than others. For example, strains that involve unjust treatment by others may be especially likely to lead to anger. Also, strains that one cannot escape from may lead to depression. Furthermore, certain emotions may be more likely to lead to some crimes than others. As suggested earlier, anger may be especially conducive to violence. Depression, however, may be more conducive to drug use. Researchers are now examining these ideas.

Strains may also lead to crime because they reduce one's level of social control (see Chapter 36, this volume). Strains often involve negative treatment by people such as parents, teachers, spouses, and employers. Such negative treatment can reduce the individual's emotional bond to these conventional others. It can also reduce the individual's investment in conventional society, particularly if the negative treatment involves such things as low grades or the termination of employment. Furthermore, negative treatment can reduce the direct control exercised over individuals (i.e., the extent to which conventional others monitor the individual's behavior and sanction rule violations). This may occur if strains such as child abuse cause individuals to retreat from conventional others. Individuals who are low in these types of control are more likely to engage in crime, because they have less to lose by doing so.

Furthermore, strains may foster the social learning of crime; that is, strains may lead individuals to associate with others who reinforce crime, model crime, and teach beliefs favorable to crime (see Chapter 38, this volume). As Cohen (1955) and Cloward and Ohlin (1960) have suggested, strained individuals may associate with other criminals in an effort to cope with their strains. For example, abused or neglected juveniles may join gangs in an effort to find acceptance and support. Individuals who are threatened by others may join gangs for protection. Also, individuals who are subject to those strains conducive to crime may develop beliefs favorable to crime. For example, individuals who are regularly bullied by others may come to believe that violence is a justifiable, or at least excusable, way to cope. Individuals who are chronically unemployed may come to believe that theft is sometimes justifiable or excusable.

Finally, individuals who experience strains over a long period may develop personality traits conducive to crime, including traits such as negative emotionality (see Chapters 31–32 and 34, this volume). Individuals high in negative emotionality are easily upset and become very angry when upset. The continued experience of strains reduces their ability to cope in a legal manner. As a consequence, new strains are more likely to overwhelm them and make them very upset. Not surprisingly, such people are then more likely to cope through crime.

Several studies have found support for these arguments; that is, strains do tend to reduce social control, foster the social learning of crime, and contribute to traits such as

negative emotionality (see Agnew, 2006; Paternoster & Mazerolle, 1994). Strains, then, may increase the likelihood of crime for several reasons, not simply through their effect on negative emotions.

Factors That Increase the Likelihood of Criminal Coping

There are a variety of ways to cope with strains, most of them legal. Juveniles who are having trouble with schoolwork, for example, might devote more time to their homework; seek help from teachers, parents, or friends; convince themselves that school is not that important; exercise or listen to music in an effort to feel better; and so on. Individuals who experience strains typically cope using legal strategies such as these. Given this fact, it is critical for strain theories to explain why some individuals choose crime as a means of coping. According to GST, criminal coping is most likely to be enacted by individuals with certain characteristics:

- *Possess poor coping skills and resources.* Some individuals lack the skills and resources to legally cope on their own. They have poor problem-solving and social skills, including skills such as the ability to negotiate with others. They possess traits such as negative emotionality and low constraint. Individuals with these traits are easily upset and tend to act without thinking. Furthermore, they have limited financial resources. Money is a great coping resource, because it allows one to purchase needed goods and services (including the services of people such as tutors, counselors, and lawyers).

- *Have low levels of conventional social support.* Not only are some individuals unable to legally cope on their own but also they lack others to whom they can turn for assistance. This assistance might include advice on how to cope, emotional support, financial assistance, and direct assistance in coping. For example, children who are having trouble in school might seek assistance from their parents, who may comfort them, give them advice on how to study, and arrange special assistance from their teachers. Individuals who are unemployed may obtain assistance from their friends, who may help them find work and loan them money.

- *Are low in social control.* Some individuals also have little to lose if they engage in criminal coping. They are unlikely to be punished if they engage in crime, because their family members, neighbors, and others do not closely supervise them and rarely impose sanctions when they do misbehave. They have little to lose if they are punished, because they do not care what conventional others, such as parents and teachers, think of them. Also, they are doing poorly in school, do not plan on going to college, are unemployed or work in “bad” jobs, and do not have a good

reputation in the community. They also do not view crime as wrong or immoral.

- *Associate with criminal others.* Other criminals model criminal coping, frequently encourage individuals to engage in crime, and often reinforce crime when it occurs. Imagine, for example, a gang member who is insulted by someone. This gang member is more likely to respond with violence because that is how other members of the gang respond to similar provocations; other gang members directly encourage a violent response, and they reinforce violent responses—most often with social approval. Furthermore, they may punish nonviolent responses. For example, gang members who do not respond to provocations with violence may be called cowards (or worse) and regularly harassed.

- *Hold beliefs favorable to criminal coping.* Some individuals believe that crime is an excusable, justifiable, or even desirable response to certain strains. For example, they believe that violence is an appropriate response to a wide range of provocation (Anderson, 1999). They learn these beliefs from others, especially criminal others. Also, as indicated previously, they sometimes develop these beliefs after experiencing chronic or long-term strains (e.g., being bullied over a long period).

- *Are in situations where the costs of criminal coping are low and the benefits high.* In particular, strained individuals are more likely to turn to crime when they encounter attractive targets for crime in the absence of capable guardians (see Chapter 33, this volume). An individual with a desperate need for money, for example, is more likely to engage in theft if he or she comes across a valuable item that is unguarded.

In sum, individuals are most likely to engage in criminal coping when they (a) are unable to engage in legal coping, (b) have little to lose by criminal coping, (c) are disposed to criminal coping because of the people with whom they associate and the beliefs they hold, and (d) encounter attractive opportunities for crime.

Researchers have examined the extent to which certain of these factors influence the likelihood of criminal coping. The results of their studies have been mixed (see Agnew, 2006). Some have found that individuals with these factors are more likely to cope with strains through crime; for example, some research indicates that criminal coping is more likely among individuals who are high in negative emotionality or who associate with delinquent peers. Other studies, however, have not found this.

Criminologists are now trying to make sense of these mixed results (see Agnew, 2006; Mazerolle & Maahs, 2000). One possibility for the conflicting results has to do with the fact that researchers often examine the preceding factors in isolation from one another. However, it may be that individuals engage in criminal coping only when their

standing on all or most of the preceding factors is favorable to such coping. Mazerolle and Maahs (2000) explored this possibility. They examined three factors: (1) low constraint, (2) association with criminal peers, and (3) beliefs favorable to criminal coping. Mazerolle and Maahs found that when all three of these factors were favorable to criminal coping, highly strained individuals were quite likely to engage in crime.

Explaining Groups Differences in Crime

Strain theories have been used primarily to explain why some individuals are more likely to engage in crime than others. Increasingly, however, they are also being used to explain group differences in crime, in particular gender, age, ethnic-racial, class, and community differences. An example of this use has already been presented.

Merton's (1938) version of strain theory has been used to explain class differences in crime. Lower-class individuals are said to engage in higher rates of crime because they have more trouble achieving their monetary goals through legal channels. Note, however, that the relationship between class and crime is not as strong as many people believe. There appears to be little relationship between class and minor crime, although lower-class individuals are somewhat more likely to engage in minor crime (see Agnew, 2009). Furthermore, middle-class individuals are more likely to engage in certain types of white-collar crime, especially corporate crime. Recent versions of strain theory have attempted to explain this by noting that middle- and upper-class individuals do sometimes experience monetary strain, especially when they compare themselves with even more advantaged others (Passas, 1997).

GST explains group differences in crime by arguing that the members of certain groups are more likely to (a) experience strains that are conducive to crime and (b) cope with these strains through crime. As an illustration, consider the strong relationship between gender and crime. With the exception of a few types of crime, males have substantially higher levels of offending than females (see Chapter 10, this volume). Part of the reason for this is that males are more likely to experience many of the strains that are conducive to crime. This includes strains such as harsh parental discipline, negative school experiences (e.g., low grades), criminal victimization, homelessness, and perhaps the inability to achieve goals such as thrills/excitement and masculine status. It is important to note, however, that females experience as much or more overall strain than males. Many of the strains experienced by females, however, are not conducive to crime. These include strains involving close supervision by others and the burdens associated with the care of others (e.g., children and elderly parents). Furthermore, females are more likely to experience

certain strains that are conducive to crime, such as sexual abuse and gender discrimination. Overall, however, males are more likely than females to experience strains that are conducive to crime (see Agnew, 2006)

Males are also more likely to cope with strains through crime. Part of the reason for this has to do with gender differences in the emotional reaction to strains. Both males and females tend to become angry when they experience strains. The anger of females, however, is more often accompanied by emotions such as guilt, shame, anxiety, and depression. This is because females more often blame themselves when they experience strains, view their anger as inappropriate, and worry that their anger might lead them to harm others. The anger of males, however, is more often accompanied by moral outrage. This is because males are quicker to blame others for their strains and to interpret the negative treatment they have experienced as a deliberate challenge or insult. These gender differences in the experience of anger reflect differences in socialization and social position. Females, for example, are more often taught to be nurturing and submissive, and so they are more likely to view their anger as inappropriate. In any event, the moral outrage of angry males is more conducive to criminal coping, especially to crimes directed against others.

Also, males are more likely to engage in criminal coping because of their standing on those factors that increase the likelihood of criminal coping. Among other things, males are higher in negative emotionality and lower in constraint. Males are lower in certain types of social support—especially emotional supports—and they are lower in many types of social control. In particular, males are less well supervised, less likely to be punished for aggressive behavior, more weakly tied to school, and less likely to condemn crime. Furthermore, males are more likely to associate with other criminals and hold beliefs favorable to crime. Males, for example, are more likely to have delinquent friends and to be gang members than are females. Finally, males are more likely to hold gender-related beliefs that are conducive to criminal coping, such as the belief that they should be “tough.”

Data provide some support for these arguments. Research does indicate that males are more likely to experience many of the strains that are conducive to crime, and studies tend to suggest that males are more likely to cope with strains through crime, although not all studies have found this (see Agnew, 2006; Brody & Agnew, 1997). Strain theory, then, can partly explain gender differences to crime. Strain theory has also been used to help explain ethnic-racial, age, class, and community differences in crime (see Agnew, 2006 for an overview; see Agnew, 1997; Eitle & Turner, 2003; and Warner & Fowler, 2003, for selected studies). The argument here is the same. The members of groups with higher rates of crime are more likely to experience strains that are conducive to crime and to cope with such strains through crime.

Recommendations for Controlling Crime

The early strain theories of Merton (1938), Cohen (1955), and Cloward and Ohlin (1960) had a major impact on efforts to control crime. These theories were one of the inspirations for the War on Poverty, which was developed under President Kennedy's administration and implemented under President Johnson. The War on Poverty consisted of a number of programs designed to eliminate poverty in the United States. While eliminating poverty was, of course, a desirable goal in itself, it was also felt that eradicating poverty would reduce other social problems, such as crime. Several of the programs that were part of the War on Poverty were directly inspired by strain theories. These programs were designed to help lower-income people achieve the goal of monetary success (or middle-class status) through legal channels. Certain of these programs remain in existence.

One such program is the National Head Start Association, which sponsors a preschool enrichment program. Head Start focuses on preschool-age children in disadvantaged areas. Such children are placed in a preschool program designed to equip them with the skills and attitudes necessary to do well in school. The program also works with the parents of these children, teaching them how they can help their children do well in school. Another program, Job Corps, focuses on older juveniles and adults. This program attempts to equip individuals with the skills and attitudes necessary to obtain a good job. Some evidence suggests that both these programs are successful in reducing crime, especially when they are well implemented (see Agnew, 2009, and Agnew, in press, for further discussion).

GST suggests still other strategies for controlling crime (Agnew, 2006, in press). These strategies fall into two broad groups. First, GST recommends reducing the exposure of individuals to strains that are conducive to crime. Head Start and Job Corps fall into this category, because their primary goal is to reduce the likelihood that individuals will experience school and/or work problems, such as working in "bad" jobs or chronic unemployment. Second, GST recommends reducing the likelihood that individuals will cope with strains through crime.

Reducing the Exposure of Individuals to Strains That Are Conducive to Crime

Several programs have tried to eliminate or at least reduce certain of the strains conducive to crime. For example, parent training programs attempt to reduce the likelihood that parents will reject their children and use harsh or abusive disciplinary methods. These programs target at-risk parents, such as teenage parents, or the parents of delinquent youth or juveniles believed to be at risk for delinquency. Among other things, such programs teach parents how to effectively

discipline their children and how to better resolve conflicts that arise. They may also encourage family members to spend more time together in pleasurable activities. Furthermore, these programs may attempt to reduce some of the stresses or strains that parents experience, such as work and housing problems. These stresses have been found to contribute to a range of poor parenting practices.

Another program that attempts to reduce exposure to strains focuses on bullying or peer abuse at school. This program attempts to make students, teachers, parents, and administrators more aware of the extent and consequences of bullying. These individuals are then given assistance in designing an anti-bullying program. Clear rules against bullying are established, these rules are widely publicized, and teachers and others closely monitor the school for bullying. Bullies are disciplined in an appropriate manner, and the victims of bullying are offered support. Still other programs attempt to reduce strains such as poor academic performance, work and employment problems, and homelessness. Many of these programs have shown much success in reducing crime (see Agnew, 2006, 2009, in press).

Still other programs recognize that, despite our best efforts, we will not be able to eliminate all strains that are conducive to crime. Teachers, for example, will likely continue to give low grades to students. We can, however, *alter strains so as to make them less conducive to crime*. For example, teachers can be taught to assign grades in a manner that is more likely to be perceived as fair by students. Likewise, police and justice professionals can adopt techniques that are more likely to be perceived as fair by individuals who are arrested and punished. Many such techniques are embodied in the restorative justice approach (see Chapter 89, this volume). In addition, we can *make it easier for individuals to avoid strains that are conducive to crime*. For example, we can make it easier for students to change teachers or schools when other efforts to deal with school-related strains fail. Or we can make it easier for individuals to move from high-crime communities where they are regularly victimized.

Finally, we can *equip individuals with the traits and skills to avoid strains*. Individuals sometimes provoke negative treatment from others, including parents, peers, teachers, and employers. This is especially true when individuals are low in constraint and high in negative emotionality. As indicated, such individuals are easily upset, tend to act without thinking, and often have an antagonistic interactional style. Not surprisingly, these individuals frequently upset other people, who may then respond with negative treatment. Parents, for example, may eventually come to reject and harshly discipline children with these traits. Several programs, however, have shown some success in teaching individuals to better manage their anger and show some restraint before acting. As such, these programs may reduce the likelihood that individuals elicit negative treatment from others.

Reducing the Likelihood That Individuals Will Respond to Strains With Crime

Although we can do much to reduce the exposure of individuals to strains conducive to crime, it is unlikely that we can entirely eliminate such exposure. For that reason, it is also important to reduce the likelihood that individuals respond to strains with crime. Several programs in this area have shown some success in reducing crime. One set of programs attempts to improve the coping skills and resources of individuals. For example, individuals may be taught problem-solving and social skills, thereby increasing the likelihood that they will be able to develop and implement legal methods for dealing with their strains. To illustrate, individuals may be taught how to respond in a legal manner if they are harassed by peers. On a related note, individuals may be taught methods for better managing their anger.

Individuals also may be provided with increased levels of social support. For example, they might be assigned mentors who provide assistance in coping. Also, a range of government assistance programs may be developed to help individuals cope when they face strains such as long-term unemployment, homelessness, and discrimination in the job market. Beyond that, steps may be taken to increase the level of social control to which individuals are subject. For example, parent training programs can increase the bond between parent and children and improve parental supervision. Also, school-based programs can raise academic performance and improve student–teacher relations. These programs reduce the likelihood that individuals will engage in criminal coping, because such coping is more likely to result in punishment, and individuals have more to lose if they are punished.

Programs may also be used to reduce association with criminal peers and alter beliefs that encourage criminal coping. For example, certain programs have shown some success in altering beliefs that are favorable to drug use. Unfortunately, it has been more difficult to convince individuals to quit juvenile gangs or stop associating with their delinquent friends. Some progress is being made, however.

Conclusion

Strain theories are based on a simple, commonsense idea: When people are treated badly, they may become upset and engage in crime. Strain theories elaborate on this idea by describing the types of negative treatment most likely to result in crime, why negative treatment increases the likelihood of crime, and why some people are more likely than others to respond to negative treatment with crime.

The strains most likely to lead to crime are high in magnitude, perceived as unjust, and associated with low social control, and they create some pressure or incentive for crime. Examples include parental rejection, harsh or abusive

discipline, chronic unemployment or work in “bad” jobs, criminal victimization, homelessness, discrimination, and the inability to achieve monetary goals. These strains lead to a range of negative emotions, such as anger. These emotions create pressure for corrective action, with crime being one possible response. Crime may allow individuals to reduce or escape from strains, seek revenge, or alleviate their negative emotions (through, e.g., illicit drug use). Strains may also increase crime by reducing social control, fostering association with criminal peers and beliefs favorable to crime, and contributing to traits such as negative emotionality. Individuals are most likely to engage in criminal coping when they lack the resources to legally cope with strains, have little to lose by engaging in crime, are disposed to criminal coping, and are in situations that present attractive opportunities for such coping.

Researchers are extending strain theory in important ways. They are using the theory to help explain group differences in crime, such as gender differences in offending. Also, the implications of strain theory for controlling crime are receiving increased attention. Agnew (2006) described still other extensions. In sum, strain theory constitutes one of the major explanations of crime and has much potential for controlling crime.

MICHAEL G. TURNER AND KRISTIE R. BLEVINS

University of North Carolina at Charlotte

The scientific study of the causes of delinquency and crime has been historically guided by theory. A good theory is said to provide a foundational lens through which to interpret and understand the manifestation of a behavior. In the field of criminology, the theoretical lens has been primarily guided by concepts germane to the fields of sociology, psychology, and biology, and the behavior to be explained is typically behavior that violates the codified laws of our society (i.e., crime and delinquency). Although isolated theories have provided empirical insight into the important factors perceived and expected to explain delinquency and crime, no single theory can adequately explain all types of crime and delinquency or all of the variation in crime and delinquency. In response to the absence of a “magic bullet” theory, scholars have begun to integrate theories in hopes of explaining a greater proportion of delinquency and crime. Theoretical integration generally involves borrowing theoretical constructs from competing theories and combining them into a single theory. Integrating theories within criminology is particularly advantageous because it allows scholars to begin to understand the behavior under study in a more complex, and potentially more complete, manner.

The purpose of this chapter is to present information on the topic of *theoretical integration* and take the reader through the following logical road map of the knowledge base surrounding integrated theories. The chapter begins with a brief discussion of the history and rationale for

integrating theories. Although brief, it is meant to provide some context within this section about how and why integrated theories have developed. Second, information on several different types of integrated theories that have emerged over the past few decades are provided: The theory and theoretical assumptions of the theory are presented, and it is shown how the theory is an integration of multiple theories or multiple concepts. It should be noted that the purpose of this section isn't meant to be exhaustive; instead, the intent is to provide the reader with a level of specificity as to how criminological theories have been integrated. Third, using the discussion in the previous section, some of the many policy implications that have (or might have) emerged as a result of integrating theories are presented. Fourth, information relating to several of the critiques surrounding theoretical integration is provided, with a discussion about how these assessments have redefined the topic. The chapter closes with an excerpt on what the future might hold in terms of further elaboration of complex integrated theories.

History, Rationale, and Methods of Integrating Theories

The history of integrated theories can be traced back to the work of Cesare Lombroso, who in the late 1800s and early 1900s refined his earlier work on the criminal man and

argued that a complete understanding of crime and delinquency requires that we account for biological, psychological, and sociological variables. Despite Lombroso's assertions, most theorizing in criminology over the first half of the 20th century focused primarily on the influence that the environment (i.e., sociology) had on the explanation of delinquency and crime.

In the latter half of the 20th century, and in partial response to the growing literature documenting that *some* theories explained *some* delinquent and criminal behavior *some* of the time, scholars began integrating theories in hopes of providing a more complete picture of why individuals violate the law. To achieve this, they began by first isolating the variables that received support across theories and, second, formulating relationships among these variables. As such, theoretical integration is more than just borrowing concepts from a variety of theories; it is the elaboration of how these concepts influence (and are influenced) by the remaining concepts.

During the past three decades, we have arguably observed the most significant growth in the development of integrated theories. The more recent approaches continue to draw primarily on factors within the environment (i.e., family and peers); however, efforts have also been made to integrate theoretical constructs from other disciplines (i.e., biology and psychology). The result of these efforts has been a variety of integrated theories that have received an increasing level of empirical attention and that have provided a baseline of knowledge from which future integrated theories could expand.

After recognizing that theoretical integration is simply one form of theorizing, what becomes a logical question of concern is whether theoretical integration is a more useful method of theoretical growth. As new theories continue to emerge and offer a unique perspective on the explanation of crime and delinquency, opportunities to integrate these theories will follow. The most promising and recognized alternative to theoretical growth in this regard is often referred to *theoretical competition*; that is, including constructs of two or more competing theories and examining which one makes more logical sense and receives greater empirical support. It remains to be seen whether theoretical competition and theoretical integration will continue to coexist as methods of theoretical growth.

Because there is no perfect way to develop a theory of delinquency and crime, there is also no perfect way to develop an integrated theory. In fact, there exists a variety of strategies to develop an integrated theory. For example, one such strategy is referred to as the *end-to-end approach*, whereby scholars combine theories while taking into account the temporal ordering of the variables included within the theory. This method allows variables to act both as causes (independent variables) as well as effects (dependent variables). A second strategy, referred to as the *side-by-side approach*, partitions cases of delinquency and crime into theories that are best at offering an explanation.

For instance, one might want to use characteristics of deviants (i.e., race, class, age, and gender) or characteristics of deviance (i.e., violent crime, property crime, and drug crime) as points where partitioning makes intuitive sense. The subsequent process would be to integrate a variety of theoretical constructs to best explain the cases in each of these empirical typologies. Finally, *up-and-down integration* (also known as *deductive integration*) is accomplished by identifying a unique level of abstraction that will allow the incorporation of other theories. For example, portions of Theory B can be subsumed into Theory A because the latter contains more abstract or general assumptions about why a particular behavior exists. Although these three methods do not account for all types of integrated theories, they are arguably the methods on which theoreticians typically rely when combining theories.

In short, it is apparent that multiple methods exist to integrate the constructs of various theories into a uniquely integrative theoretical approach. The purpose of the next section is to offer insight into the many different integrated theories that have emerged over the past two to three decades.

Types of Integrated Theories

Although integrated theories have a lengthy history, it is only within the last few decades that these theories have been recognized and accepted as purely integrated theories. This section focuses on the descriptions of some of the more commonly recognized integrated theories. Again, it is not the intention of this section to provide detail on all of the integrated theories; instead, the integrated theories identified in the following paragraphs should provide the reader with an understanding of the various types of these theories.

Elliott, Ageton, and Canter's Integrated Theory

In 1979, Delbert Elliott and his colleagues proposed one of the more widely recognized integrated theories (Elliott, Ageton, & Canter, 1979). Borrowing concepts from strain, social learning, and social control theories, they proposed that individuals follow one of two pathways into delinquency. In the first pathway, individuals with lower levels of social control begin interacting with delinquent peers. In this pathway, the reduction in social control allows individuals to associate with other delinquents, experience peer pressure from these peers, and learn how to commit delinquent offenses. In the second pathway, individuals with higher levels of social control at some point experience the failure to achieve positively valued or conventional goals. As a result of this experience, individuals begin associating with delinquent peers, experience peer pressure from these peers, and learn how to commit delinquent offenses. In short, the theory argues

that individuals who experience both low and high levels of social control are capable of becoming delinquent. The central variable that plays an important role in delinquent development in both pathways is one's exposure and commitment to delinquent peers.

It is important to point out that Elliott et al.'s (1979) theory is an integrated theory because it borrows concepts from three reputable theories (strain, social control, and social learning) and articulates how these concepts relate to one another. More specifically, the social control and strain aspects of the theory are not proposed to have direct effects on delinquency; instead, each of these variables operates through the exposure and commitment to delinquent peers. It logically follows that the exclusion of delinquent peers from the theoretical models would limit the theory's ability to explain delinquent and criminal behavior. Therefore, it is the integration of these three theories that provides the foundation to understand the etiology of crime and delinquency.

Thornberry's Interactional Theory

In 1987, a similar integrated theory was proposed by Terence Thornberry. Much like Elliott and his colleagues (1979), Thornberry borrowed elements from social control and social learning theories; specifically, he proposed in interactional theory that delinquency is primarily a function of individuals associating with delinquent peers. The opportunities to associate with these peers is argued to be the direct result of the weakened social bonds (i.e., social control) experienced as individuals progress through the life course. Unlike Elliott et al., Thornberry excluded any conceptual involvement of strain theory in the advancement of interactional theory.

Two distinguishing features of Thornberry's (1987) interactional theory set it apart from other integrated theories, in general, and Elliott et al.'s (1979) theory, specifically. First, interactional theory emphasizes the presence of reciprocal effects in the causal structure of the onset of delinquency. Unlike most theories that assume or identify causal pathways in one direction (typically from left to right), interactional theory assumes that important variables within the model possess reciprocal or feedback effects. For example, although weakening social bonds might lead an individual to associate with delinquent peers, it is also theorized that the association with delinquent peers further weakens social bonds. Second, interactional theory places an emphasis on the developmental nature of the etiology of delinquency and crime. In other words, Thornberry articulated a theory that explains the onset, persistence, and desistence of delinquency and alters the importance of the concepts at these various stages of the life course. It is notable that although parental attachments (i.e., social bonds) are important in the explanation of the onset of delinquency early in the life course, these same concepts become relatively weaker in the explanation of the persistence in

delinquency as individuals navigate the adolescent period of development.

Agnew's General Strain Theory

In 1992, Robert Agnew recognized that Merton's traditional strain theory possessed a variety of limitations that restricted the empirical support it received. In so doing, Agnew reconceptualized traditional strain theory into a general strain theory by shifting the focus from social class or cultural variables, capturing the emotion of the situational context in which delinquency and crime develop.

Agnew (1992) began by recognizing three sources of strain an individual can experience over the life course. First, similar to traditional strain theorists, Agnew identified the actual or anticipated *failure to achieve positively valued goals* as a source of strain. For example, individuals might feel strain because they cannot achieve economic or financial success, or they may not be able to achieve a particular status within high school. Second, Agnew identified the actual or anticipated *removal of positively valued stimuli* as a potential source of strain. This strain might occur, for example, when individuals experience the death of someone close to them, when an intimate or dating relationship ends, or when someone is terminated from a job he or she enjoyed. The point is that something they coveted has been removed from their life. Finally, Agnew identified the actual or anticipated *presentation of negative stimuli* as the final source of strain that could be experienced by individuals. Examples of this last source of strain include residing within an abusive household, attending a dangerous school, or working under the supervision of a supervisor who manifests negative or harassing behaviors.

The primary assumption of general strain theory is that as the levels of strain increase, individuals are more likely to engage in delinquency and crime. However, even in the most adverse or stressful situations that may be caused by strain, some individuals are capable of not responding in delinquent or criminal ways. Recognizing this outcome, Agnew (1992) identified several constraints that might condition individual responses to strain. These conditioning variables fall into two categories: (1) conditioning factors that *increase* the probability of manifesting a delinquent or criminal response and (2) conditioning factors that *decrease* the probability of manifesting a delinquent or criminal response. In terms of conditioning responses identified to increase delinquent and criminal outcomes, Agnew highlighted important factors, such as self-control, the association with delinquent peers, and the internalization of antisocial beliefs. Alternatively, in terms of conditioning responses identified to reduce delinquent and criminal outcomes, Agnew directed us to factors such as individual coping strategies, the receipt of social supports from others, the presence of social bonds, and the fear of formal sanctions. In short, the conditioning responses are typically important

variables from other prominent criminological theories that are integrated into the articulation of general strain theory.

General strain theory is considered an integrated theory for two reasons. First, Agnew effectively integrated social and psychological constructs; that is, socially (or within certain situations), individuals may experience events or circumstance with which they are unfamiliar (i.e., being fired from a job or losing a parent), but psychologically they must somehow respond to this adverse situation. Second, as highlighted in the preceding text, Agnew included a variety of conditioning responses that are “borrowed” from other competing theories. It is at this juncture that theoretical integration is manifested within the general strain theory.

Moffitt’s Dual Taxonomy Theory of Offending

In 1993, Terrie Moffitt proposed a theory that not only integrates concepts derived from biology, psychology, and sociology but also approaches the explanation of delinquency and crime from a developmental perspective. Moffitt began by documenting that concealed under the aggregate age–crime curve are two types of offenders. One type of offender, which she called the *life-course-persistent offenders*, begins offending early in the life course, persists in offending at high levels during adolescence, and continues a life of crime well into adulthood. In other words, stability of behavior is the key to understanding life-course-persistent offending. A second type of offender, which she called the *adolescence-limited offenders*, begin their offending careers during the adolescent period of development, offend for a short period of time, and desist as they enter into adulthood. Whereas stability is the key to understanding life-course-persistent offending, discontinuity is the key to understanding adolescence-limited offending. With two distinct types of offenders, Moffitt made an argument that each type of offender is in need of its own theoretical explanation.

The theoretical causes of life-course-persistent offending are found very early in the life course. Specifically, Moffitt (1993) suggested that the co-occurrence of individuals being born with neuropsychological deficits and parents failing at their parenting responsibilities creates an increased likelihood that individuals will begin down a pathway of life-course-persistent offending. It should be noted that experiencing either one of these risk factors in isolation is unlikely to set an individual on a life-course-persistent trajectory of offending; instead, it is the interaction of these two factors that increases the odds of following such a pathway of development.

Compared with the life-course-persistent offenders, adolescence-limited offenders are a more prevalent, yet less serious type of offender. Because the onset of offending for adolescence-limited offenders begins in adolescence, Moffitt (1993) identified risk factors during this developmental stage as the precursors to delinquency. Specifically,

adolescence-limited offenders are theorized to begin offending as the result of experiencing the maturity gap (i.e., the gap between reaching biological maturity [puberty] and being socially accepted into adult social roles) or modeling behaviors (at a less serious level) of their life-course-persistent counterparts. In short, adolescence-limited offenders begin offending mainly as a result of environmental causes of delinquency.

Each of these theoretical articulations involves integrating biological predispositions with social conditions that accentuate (or permit) the individuals to offend. In short, Moffitt’s (1993) theory (at least the explanation of life-course-persistent offending) is referred to as a *biosocial approach*, because it proposes that individuals will become serious offenders when those with a biological predisposition to offend are raised in a social environment that fails to correct bad behavior. It is important to note that the possession of either of these variables (i.e., neuropsychological deficits or poor parenting) in isolation is not determinate of life-course-persistent offending; instead, it is the co-occurrence or interaction of these variables that is particularly detrimental to the individual.

Cullen’s Social Support Theory

In 1994, Francis T. Cullen, in his presidential address to the Academy of Criminal Justice Sciences, put forth a theory that focused on the impact of social support and its effects on individual and aggregate rates of criminality. Unlike the more traditional integrated theories that identify important factors from different theories and then integrate them into a single theory, Cullen advanced an integrated theory that identifies a common theme that is rooted within a variety of theories at different levels of explanation; that is, he highlighted the importance of social support and its impact in the implication of delinquency and crime. In so doing, he advanced 13 propositions that link social support either implicitly or explicitly to the explanation of crime and delinquency. Instead of articulating each proposition verbatim, the subsequent text presents the propositions in a thematic format.

First, at the macrolevel, Cullen (1994) predicted an inverse relationship between levels of social support and crime in that cities, states, and countries with more social support are identified as having lower rates of delinquency and crime. Second, individuals who receive and/or provide greater levels of social support are less likely to be involved in delinquency and crime. Third, higher levels of social support are theorized to reduce the impact of other criminogenic risk factors (i.e., strain and exposure to deviant peers). Fourth, and related, higher levels of social support correspond with a higher likelihood of desistance from criminal activity. Fifth, increased levels of social support are theorized to correspond with more effective police and correctional agencies. Finally, higher levels of social support result in reduction in the likelihood to be victimized.

Cullen's (1994) theory of social support is a unique attempt at theoretical integration, because the theory does not subsume several theories under a general theory. Instead, Cullen highlighted how the construct of social support becomes the central causal process within a variety of competing theories. In short, social support has a direct causal effect on crime, it has a direct causal effect on variables theoretically and empirically related to crime (i.e., social control and strain), and it has a conditioning effect on variables related to crime.

Tittle's Control Balance Theory

In 1995, Charles Tittle proposed an integrated theory known as *control balance theory*, which attempts to advance traditional control-based theories that proposed that the breakdown in controls (regardless of their source) would lead to delinquency and crime. In doing so, the focus turns to understanding how an individual's control ratio can predict the likelihood and type of deviance.

In terms of the likelihood or probability of deviance, control balance theory recognizes that individuals are controlled (like most traditional control-based theories), but it also recognizes that individuals exercise control over other individuals. Therefore, the theory predicts that the *probability* and *type* of deviance depend on the amount of control to which an individual one is subject relative to the amount of control he or she can exercise over others. In situations where there is control balance (i.e., equal amounts of control within the control balance equation), the probability of deviance is close to or equal to zero. As the control ratio becomes imbalanced (moving in either direction away from being balanced), however, then the individual's probability of involvement in deviance, delinquency, and crime increases.

Control imbalance can occur in one of two directions. First, as an individual's control ratio becomes imbalanced in the direction of having more control over others (relative to the amount others have over him or her), and then the individual experiences a *control surplus*. On the other hand, as the control ratio moves in the opposite direction (being subject to greater levels of control than the individual has over others), the individual experiences a *control deficit*. In either case, the further one moves toward the extremes of control surplus or control deficit, the more likely he or she will be to participate in deviance, delinquency, and crime.

In an effort to theoretically explain the types of behavior in which an individual will engage, Tittle (1995) again relied on the control ratio. It is theorized that individuals experiencing a control deficit engage in behaviors that are likely to adjust their control ratio back to control balance. Tittle identified three broad categories of behavior that are likely to be manifested by individuals experiencing a control deficit: (1) predatory acts, (2) defiant acts, and (3) submissive acts. Alternatively, individuals experiencing a control surplus engage in behaviors that are likely to accentuate (or further

advance) their surplus of control. Again, Tittle identified three broad categories of behavior that are likely to be manifested by individuals experiencing a control surplus: (1) acts of exploitation, (2) acts of decadence, and (3) acts of plunder.

Control balance theory is considered an integrated theory because it captures two important themes related to control and integrates them into a single theoretical explanation of delinquency and crime. Whereas other integrated theories rely on control-based theories as a source of integration, no other criminological theory relies on both mechanisms of the control process to predict delinquent or criminal involvement.

Colvin's Differential Coercion Theory

In 2000, Mark Colvin advanced an integrated theory that shifted the focus from an explanation of the etiology of delinquency and crime to the explanation of chronic offending. Using the concept of coercion as the organizing theoretical construct, Colvin argued that chronic offenders suffer from a variety of social and psychological dynamics brought on by destructive coercive forces.

Colvin (2000) began with the premise that social control has multiple dimensions. The first dimension is the degree of *coercion* in how the social control is applied. Although there is sure to be a continuum, Colvin provided a typology with two outcomes: (1) noncoercive and (2) coercive. The second dimension is the degree of *consistency* with which the social control is applied. Again, Colvin provided two potential outcomes to this dimension: (1) consistent and (2) erratic. Combining the elements of coercion and consistency in the application of social control, Colvin created a 2×2 matrix with four possible outcomes. Type 1 is identified as noncoercive consistent control, Type 2 is identified as noncoercive erratic control, Type 3 is identified as coercive consistent control, and Type 4 is identified as coercive erratic control.

Colvin (2000) argued that each type of control has its own set of social-psychological outcomes that manifest themselves into behavioral differences. Social-psychological outcomes for Type 1 (noncoercive, consistent) include low anger, high self-efficacy, high self-control, and an internal locus of control. Individuals within Type 1 will also manifest a strong predisposition to behave prosocially and a low probability of criminal behavior. Turning to Type 2 (noncoercive, erratic) social-psychological outcomes, Colvin noted that these individuals will have low anger, high self-efficacy, low self-control, and an internal locus of control. In terms of how these outcomes are translated to behaviors, Colvin predicted that these individuals will have a predisposition for minor nonpredatory street and white-collar crime and a strong tendency to explore deviant pleasures. Individuals identified to correspond with Type 3 (coercive, consistent) social-psychological outcomes are expected to possess high self-directed anger, low self-efficacy, rigid self-control,

and an external locus of control. The behavioral outcomes associated with this category include a low probability of prosocial behavior, a predisposition toward mental illness, and some potential for enraged assault or homicide. Finally, social-psychological outcomes for Type 4 (coercive, erratic) include high self-directed anger, low self-efficacy, low self-control, and an external locus of control. Colvin predicted that these individuals will have a predisposition for serious predatory street crime and a strong probability of chronic offending.

In short, Colvin's (2000) differential coercion theory predicts that coercion leads to social-psychological deficits that translate to consistently disruptive behavioral outcomes. It is expected that these coercive relations can emerge within a variety of environments, including, but not limited to, the home, school, workplace, peer groups, and state bureaucracies. It is also expected that individuals may experience an accumulation of coercion that has been distributed from more than one environment. This accumulation of coercion is expected to further increase the probability of the individual engaging in criminal behavior over the life course.

In terms of the relevance of differential coercion theory as an integrated theory, it should be highlighted that Colvin (2000) relied on the concept of social control and how it is applied to predict several reputable social-psychological outcomes present within extant theory. In so doing, an integrated theory is created that draws on how well-defined social constructs and their influence on social-psychological processes lead to delinquent and criminal behavior.

Policy Implications of Integrated Theories

Much like traditional theories, each integrated theory has implications for the development of policies designed to reduce delinquency and crime. Because integrated theories are generally perceived to be more complex than traditional theories, it stands to reason that their implications generally tend to be more complex. Using the integrated theories discussed in the previous section, this section offers a variety of policy implications derived from the aforementioned theoretical developments.

Implications of Elliott, Ageton, and Canter's Integrated Theory

The inclusion of theoretical concepts from three competing mainstream theories offers a unique, yet challenging, set of policy implications. According to the principles of the theory and the initial focus on the levels of social control, it follows that policies will be determinative on the basis of whether individuals are experiencing low or high levels of social control. For those experiencing lower levels of social control, policies should initially be geared toward increasing levels of social control. Most importantly, however, policies emanating from Elliott et al.'s (1979) integrated

theory should focus on reducing access and exposure to delinquent peers, because it is this construct that rises in the level of importance in the explanation of delinquent and criminal involvement.

Implications of Thornberry's Interactional Theory

Similar to the policies identified in the discussion of Elliott et al.'s (1979) integrated theory, the policies emerging from Thornberry's (1987) interactional theory are relatively complex and involve focusing on mechanisms of building social controls and decreasing access to delinquent peers. What makes interactional theory unique is that the policy initiatives are developmental specific; that is, because the importance of the theoretical factors fostering crime and delinquency vary over the life course, the policy initiatives seeking to impact delinquency and crime should also be different depending on the age of the individual. In childhood, programs designed to build and strengthen familial relationships would provide a foundation to reduce the likelihood of the onset of delinquency. In terms of the persistence in delinquency and crime, effective policies or programs would emerge if they were geared toward the reduction of exposure to delinquent peers during the adolescent period. However, because Thornberry placed significant emphasis on the reciprocal effects of the social bonding and delinquent peer variables during childhood and adolescence, it stands to reason that a dual-pronged policy approach focusing on both sources of delinquency would provide the most complete program initiative to the reduction of these behaviors.

Implications of Agnew's General Strain Theory

Given that all individuals will experience several of the strains articulated by Agnew (1992), it stands to reason that the policy implications relevant to general strain theory are not geared toward reducing the experience of strain. Instead, policies from a general strain tradition might be more effective if they are focused on enhancing the conditioning factors that result in prosocial responses to strain. For example, programs that educate individuals in how to manage their anger or channel the energy related to their anger into positive directions (i.e., positively cope with strain) would be particularly advantageous to reducing delinquency and crime. On a related note, policies geared toward initiating programs targeting the development of self-control early in the life course would provide an additional prosocial mechanism for responding to strain. In terms of familial and community alternatives, programs guided toward the development or enhancement of social support networks would provide an individual with access to external supports when faced with a crisis. In short, the policy implications for general strain theory have the highest probability of being successful if they

focus on the concepts related to individuals' responses to experiencing strain.

Implications of Moffitt's Dual Taxonomy Theory of Offending

Because Moffitt's (1993) theory partitions the theoretical explanation of delinquency and crime into two distinct theories, it logically follows that the policy implications of the theory are approached in a similar bifurcated process. Not surprisingly, most of the aggressive and impactful policy implications are geared toward life-course-persistent offenders; specifically, because this pathway of development is argued to be difficult to redirect, the policies need to be aimed at reducing the likelihood that individuals will *begin* offending early in the life course. Programs such as nurse home visitations to help disadvantaged parents provide appropriate parenting strategies to children experiencing deficits associated with neuropsychological disorders have been found to be particularly successful at redirecting the pathway of the troubled child. On the other hand, because the adolescence-limited population is likely to discontinue their offending as they enter into adult social roles, the policies geared toward this population are likely to be much more hands off. For example, this population might particularly benefit from after-school programs that focus on keeping youth actively involved in prosocial and/sports-related activities during the peak time of adolescent offending.

Implications of Cullen's Social Support Theory

Arguably one of the more simplistic integrated theories, Cullen's (1994) social support theory also receives the title of the theory with one of the most straightforward policy initiatives; that is, crime and delinquency at all levels (i.e., individual, family, neighborhood, rates within cities, states, and across the nation) would be reduced if increases in social support were observed. Moreover, offending over the life course would begin later in life and have a shorter duration, and desistance would be enhanced if only social supports were increased. Finally, the probability of experiencing a victimization and the victimization rate would both decrease if social supports across society were enhanced. In summary, the primary policy implications related to Cullen's social support theory are focused toward developing and enhancing social supports within individuals or within the larger neighborhood environment.

Implications of Tittle's Control Balance Theory

The policy implications of Tittle's (1995) control balance theory are significantly more complex than those identified for the theories just discussed. If the goal of a policy is to implement a program (or set of programs) to reduce delinquency, then using control balance theory implies that policies should be aimed at developing programs to keep

individuals' control ratio at a balance and/or providing assistance to individuals to manage or restrict their behavior when they are experiencing a control imbalance. These policy initiatives appear to be more reasoned for individuals experiencing a control deficit; however, they appear to be more suspect for those experiencing a control surplus. Specifically, programs designed for individuals experiencing a control deficit could arguably resemble those designed for general strain theory discussed earlier. Designing programs to convince individuals who are experiencing a control surplus to refrain from extending their control, or relinquish their control, appears to be a more daunting task.

Implications of Colvin's Differential Coercion Theory

Programs designed to reduce delinquency and crime using the differential coercion theoretical framework would primarily target efforts to reduce the likelihood that coercion is destructively applied to individuals and secondarily target the social-psychological outcomes related to coercion. Colvin (2000) highlighted four possible outcomes through which controls can be manifested. The most compelling nondelinquent outcome is related to Type 1 (noncoercive, consistent). As such, parents and other individuals delivering social control might be educated or informed on the benefits related to Type 1 and the detriments associated with each of the remaining possibilities of delivering control. Assuming that some individuals will experience coercive types of control, programs might also be effective if they seek to strengthen the social-psychological dynamics (i.e., self-control) related to experiencing coercion.

Critiques of Integrated Theories

Although integrated theories have been important in providing an arguably more complex, yet complete, understanding of the causes of delinquency and crime over the life course, they are not without their limitations. To place these limitations into context one needs only draw on the literature documenting the characteristics of a "good" or "effective" theory. This section identifies and elaborates on some of the criticisms waged against integrated theories.

First, some scholars have claimed that some of the components of theories used in theoretical integration are based on opposing or competing assumptions. For example, a foundational assumption of social-control-based theories is that involvement in delinquency and crime is natural and thus individuals do not need any simplistic or elaborate means through which to learn the behavior. On the other hand, a foundational assumption of social learning theories is that individuals can manifest the behavior only once they have participated in a process through which the behavior was learned. Integrated theories that have used components of each of those two

theories (i.e., Elliott et al.'s [1979] integrated theory and Thornberry's [1987] interactional theory) have endured extensive scrutiny as to which of those two assumptions prevails in the theory's development. It is clear that both of those assumptions cannot be true, because assuming one denies the existence of the other.

Second, the rise in theoretical integration is based on somewhat questionable assumptions. For example, compared with the approach of theoretical competition to advance scientific knowledge, some scholars argue that integrating criminological theories will result in the advancement of knowledge about the causes of delinquency and crime at an exceedingly faster rate. This assumption, however, is relatively shaky at best. Scholars have argued that theoretical competition is superior because it forces theorists to search for innovative ways of developing theoretical models.

Third, and related, theoretical integration, if not carried out carefully and thoughtfully, could potentially lead to sloppy theorizing. The integration of concepts into a theoretical framework must make logical and intuitive sense. If concepts are integrated only because they have been found to be strong predictors in isolated theories, then scholars risk jeopardizing theoretical parsimony, at best, and confounding theoretical principles, at worst. To provide an analogy, if individuals chose food from a buffet only because it was tastefully delicious without giving thought to whether the food was healthy, then individuals sacrifice a well-rounded, nutritionally balanced meal. In short, although integrated theories have been helpful in providing an arguably more complete understanding of the causes of delinquency and crime, their complexity makes them susceptible to a variety of potential limitations.

Conclusion

This chapter has not explored all of the sources or types of theoretical integration. In fact, a school of integration that is more eclectically based and approaches theoretical integration from a constructivist and postmodern stance was not discussed. The purpose of this exclusion is not because of an absence of scholarly interest in these approaches within the criminological community; instead, the exclusion is primarily based on the necessity to offer readers a variety of the testable modernist approaches that have at their focus a vision of the application of deterministic approaches to understanding the development of delinquency and crime.

It is often recognized that the world in which we live is becoming increasingly complex, and future generations face challenges unlike those that were faced by our predecessors. It should logically follow that the increasing complexity potentially impacts the causes of delinquency and crime by further opening up new fields of inquiry and recognizing and reconsidering the impact of risk factors from

a variety of sources. Coexisting with the changes in society is a growth in the complexity of the theoretical articulations attempting to explain delinquency and crime. Although traditional theories have approached the development of theories within an intradisciplinary fashion or from a single level of inquiry (i.e., macro vs. micro), more recent theoretical attempts have integrated concepts from a variety of disciplines, at multiple levels, and have recognized the reciprocal nature of relationships between concepts.

The development of integrated theories has primarily relied on concepts within sociological criminology to provide an integrative foundation; that is, many of the integrated theories listed in this chapter (and those not listed) have generally had a strong reliance on concepts germane to learning and control theories while having secondarily relied on strain theories. On one level, these efforts demonstrate the field of criminology's strong 20th-century tradition of limiting the causes of delinquency and crime to factors existing within the environment. As the field of criminology has matured, however, a significant emphasis has more recently been placed on integrating theories across disciplines. Isolating components of biological and psychological determinism and theoretically explicating how these factors could potentially interact with or become accentuated within the environment in which we live has proved to have a profound effect on the explanation of delinquency and crime over the life course. Moffitt's (1993) work is perhaps the most blatant example of this type of interdisciplinary theoretical integration.

In closing, it is expected that future efforts at theoretical integration will continue to cross disciplinary boundaries, include multiple levels of analysis, and rely on more advanced statistical and methodological tools to impact the testability of the theory. It is hoped that future integrated theories are capable of capitalizing on the complexities and nuances that are experienced within an individual's daily life. The increased precision associated with the refinement of existing, and the development of future, integrated theories, are likely to result in theoretical and empirical validity associated with the explication of delinquency and crime.

CRIMINAL JUSTICE THEORIES

PETER KRASKA

Eastern Kentucky University

What is criminal justice theory? Strangely, few academics in criminal justice studies would have a clear answer. Despite the large number of academic programs and scholarly works dedicated to studying criminal justice, the field has hardly asked, let alone answered, this fundamental question (Bernard & Engel, 2001; Duffee & Maguire, 2007; Hagan, 1989; Kraska, 2006; Marenin & Worrall, 1998). Given that a theoretical infrastructure is the intellectual and conceptual core of any legitimate area of study, the time is past due to begin recognizing and developing a theoretical foundation explicitly intended to make theoretical sense of criminal justice.

It is not that criminology and criminal justice studies scholars are not experienced with theory and the activity of theorizing. Researchers in the field have amassed an impressive body of theoretical work. The focus of this work, however, has concentrated mostly on answering the “why” of crime and explaining crime rates. When the term *theory* is used in the field, it usually refers to crime theory. Criminology theory courses and theory textbooks concentrate almost exclusively on explaining crime. Theoretical research in the field, as evidenced by the articles published in the journals *Criminology* and *Justice Quarterly*, mostly test preexisting explanations for crime. The field’s theoretical infrastructure is built on explanations of crime, not criminal justice.

An underlying assumption in the field is that the discipline of criminology is more interested in explaining the why of crime and thus by nature is more theoretically oriented. It

follows, then, that studying criminal justice is necessarily a policy-based pursuit more interested in effecting practical crime-control initiatives, as derived from theories of crime (Gibbons, 1994). Studying criminal justice is tacitly relegated to the limited role of discerning “how to” and “what works”—laudable objectives, but incomplete insofar as understanding the nature of our formal reaction to crime. Dantzker’s (1998) delineation between criminology and criminal justice is typical of this view:

Criminology is the scientific study of crime as a social phenomenon—that is, the theoretical application involving the study of the nature and extent of criminal behavior. Criminal Justice is the applied and scientific study of the practical applications of criminal behavior—that is, the actions, policies, and functions of the agencies within the criminal justice system charged with addressing this behavior. (p. 107)

Are not both criminology and criminal justice studies diminishing their theoretical integrity with this conception? Surely the study of criminal justice, by both criminological and criminal justice scholars, has involved far more than merely describing its functioning and devising means of crime control. There is no reason that the study of criminal justice cannot be approached in the same way Dantzker (1998) views the study of crime. By slightly modifying his quote, criminal justice studies could similarly be viewed as “the scholarly examination of criminal justice as a social phenomenon—that is, the theoretical application involving

the study of the nature and extent of criminal justice behavior.” The notion that the activity of theorizing criminal justice phenomena can somehow be excluded is not only erroneous but also highly damaging to the disciplinary integrity of criminal justice studies.

Some traditional criminological theorists might take exception to this view. After all, they would argue, crime theory has already been used as the foundational material for developing *models* of criminal justice functioning (see Einstatder & Henry, 1995). This approach to understanding criminal justice takes traditional crime theories and infers a model of criminal justice functioning based on that particular conception of crime causation. Although modeling criminal justice functioning does shed important theoretical light on the system, even those involved in the activity admit that these models do not constitute the development of theory (Einstatder & Henry, 1995). This exercise also reinforces the notion that there can be no other theoretical foundation for understanding criminal justice behavior besides those preexisting theories designed to make theoretical sense of crime.

Some critical criminological theorists might also take exception. Critical criminology has a rich body of work theorizing the behavior of the state, the legal apparatus, trends in social control, and oppressive crime control policies. In fact, compared with their analysis of criminal justice behavior, explaining lawbreaking has been a secondary pursuit. This is one reason critical scholarship often seems out of place in most criminological theory textbooks: Their object of study—an oppressive crime control apparatus—does not coincide well with theories focused only on crime causation. Even when critical criminologists explore the causes of crime, they most often focus on the oppressive features of how the state differentially defines acts as crime among marginalized groups (again, focusing on state behavior). Seen this way, critical criminology is more engaged in theorizing criminal justice than crime.

Criminal Justice Theory: Varieties and Possibilities

Theorizing crime has proved to be a complex endeavor. The object of study is difficult to identify and agree on, a plethora of theories compete for prominence, and determining the strength and worth of these theories is wrought with controversy and conflicting evidence. This description is not meant as an indictment; instead, criminological theory’s complexity and conflicts render it dynamic and intellectually stimulating.

Theorizing criminal justice possibly harbors even more potential for this type of complexity and stimulation. The central reason is the multifaceted nature of the object of study. The entity called *criminal justice* actually comprises numerous objects of study—including the criminal justice system; each of the major components within that system (police, courts, corrections, juvenile justice); crime control

agencies and practices that fall outside the formal criminal justice system (private sector controls, social services); and other participants in criminal justice, including, but not limited to, academic researchers, the media, the legislative body, and the public.

The following questions are just a sample of the types of inquiry scholars pose when theorizing criminal justice:

- How do we best make theoretical sense of the criminal justice apparatus’s (CJA) long-term historical development?
- What accounts for the steep growth in power and size of the CJA over the last 30 years?
- How do we best make theoretical sense of current and possible future trends associated with the CJA?
- On what theoretical basis can we best understand various controversial issues facing the CJA (e.g., racial profiling, death penalty, erosion of constitutional safeguards, privatization, etc.)?
- On what theoretical basis can we best make sense of past and current criminal justice reform efforts, including what drives them and why they succeed or do not?
- How does the CJA affect the larger society in which it operates; conversely, what societal forces shape the CJA?
- How do we best make theoretical sense of the behaviors of criminal justice practitioners?
- What best explains the internal functioning and practices of criminal justice agencies?

These questions demonstrate that the field’s crime theories, because they have been constructed specifically to explain crime, are insufficient for providing adequate answers. Attempting to explain the behavior of the state, public agencies, the criminal law apparatus, trends in crime control thinking and practice, private crime control organizations, and trends in social control necessitate a theoretical infrastructure unique to these unique objects of study.

Numerous approaches to developing criminal justice theory are possible. One was already mentioned: constructing models of criminal justice functioning based on differing theories of crime. David Duffee (1990) took the more traditional approach by attempting to articulate a general theory of criminal justice grounded in the context of local communities. Of course, the development of a grand theory that accounts for all social, political, economic, and cultural influences would likely be an impractical undertaking. His more recent work (Duffee & Maguire, 2007) essentially argues for the same type of theory work advocated in this chapter. Another avenue has been to answer specific theoretical questions about a specific object of study. David Garland (2001a), for example, limits his theoretical analysis to the question of what accounts for the rapid growth of the criminal justice system over the last 30 years (focusing primarily on the correctional subsystem). Other researchers concentrate on explaining individual practitioner behavior—such as why some police officers engage in corruption. Finally, some

academics have worked on developing normative theories of criminal justice, concentrating on philosophical principles intended to guide criminal justice practices (Braithewaite & Pettit, 1990; Ellis & Ellis, 1989).

Theoretical Orientations: Infrastructure Beginnings

The problem addressed here has been carefully framed as one of recognition and accessibility. If one conceives of criminal justice theory as a body of literature attempting to make theoretical sense of the various objects of study noted earlier, the problem also lies in the labels that are used to identify particular areas of scholarship.

Labels signify well-guarded intellectual territory. And has already been established, the label *criminal justice studies* is associated with atheoretical research and writing. Accordingly, even groups of scholars targeting their theoretical efforts explicitly on criminal justice phenomena would likely resist having their work identified as “developing criminal justice theory.” They would instead label their endeavors theories of *social control* (sociology proper, sociolegal studies, and sociology of punishment), theories of *late-modern trends in crime control* (punishment and governmentality studies), theories of *oppression* (critical criminology), or theories of *public organization* (public administration). Despite a lack of recognition and conscious pursuit of a theoretical project, there exists a substantial amount of theoretical work about criminal justice phenomena that can be conceived credibly as criminal justice theory.

One good example is the rigorous theoretical work in sociolegal studies and in the sociology of punishment. Here we have a rich intellectual project targeted at theorizing recent shifts in the crime control apparatus (see, e.g., Bauman, 2000; Garland, 1997, 2001a, 2001b; O’Malley, 1999, 2000; Rose, 2000; Simon, 1995; Simon & Feeley, 1994). Theorizing criminal justice in this instance is contextualized within the field of *social control*, which probably accounts for why this highly informative body of work has not had a significant impact on mainstream criminal justice and criminology literature and textbooks. Its influence is starting to take hold, though, in particular in the works of David Garland (*The Culture of Control: Crime and Social Order in Contemporary Society*, 2001a) and Jonathan Simon (“The New Penology: Notes on the Emerging Strategy of Corrections and Its Implications,” Feeley & Simon, 2006; and *Governing Through Crime: How the War on Crime Transformed American Democracy and Created a Culture of Fear*, Simon, 2007).

Another interesting example can be found in the field of critical criminology. For the last 25 years, scholarship in this area has examined the state’s oppression of marginalized groups (women, the poor, racial minorities, homosexuals) by means of the criminal justice system. This body of work could in fact be viewed legitimately as far more concerned with

developing theories of crime control, specifically, oppressive state behavior, as opposed to crime behavior (see, e.g., Arrigo, 1999; Barak, Flavin, & Leighton, 2001; Martin & Jurik, 1996; J. Miller, 1996; S. L. Miller, 1998; Milovanovic & Russell, 2001; Parenti, 1999; Reiman, 2001; Shelden, 2001). This is the reason critical criminological theory fits awkwardly into traditional crime theory textbooks: The bulk of its explanatory attention concentrates on the behavior of the law, the government, and/or the state. Despite these various avenues for developing criminal justice theory, the field still does not have a well-recognized theoretical infrastructure about criminal justice.

To begin the process of rectifying this situation, Kraska (2004, 2006) has published two works that advance the obvious approach of identifying and articulating the contours of eight different theoretical orientations found in traditional and contemporary scholarship about the criminal justice system and trends in crime control.

A useful first step in mapping the vast terrain of criminal justice theory, therefore, would be to identify and elucidate the basic tenets of the various theoretical orientations that attempt to make sense of criminal justice phenomena. A *theoretical orientation* is simply an interpretive construct: a logically coherent set of organizing concepts, causal preferences, value clusters, and assumptions that work to orient our interpretations and understanding of criminal justice phenomena. The goal would not be to develop a single, testable criminal justice theory; to the contrary, the objective would be to illuminate the multiple theoretical lenses (broad-based interpretive constructs) crime and justice scholars use for helping people understand the behavior of the criminal justice system and trends in crime control.

The network of governmental agencies responding to the crime problem is universally known as the *criminal justice system*. Several theoretical orientations in the field are easily identified—the systems theoretical orientation being the most obvious. Most academics would agree that the systems framework has dominated the field’s thinking and research about criminal justice. The framework is derived from the biological sciences, Parson’s (1951) structural functionalism, and organizational studies. It has a strong reformist element, emphasizing the importance of enhancing criminal justice system coordination, efficiency, rational decision making, and technology.

Table 40.1 illustrates the major features, concepts, and ideas associated with the eight criminal justice theoretical orientations.

Perusal of these eight orientations should demonstrate that the field actually has a rich set of theoretical lenses through which to make sense of criminal justice phenomena, aside from theories about crime. The multitheoretical approach depicted in Table 40.1 not only catalogs the diversity of thinking in the field of study but also avoids the ethnocentric tendency in academics to view phenomena through a single theoretical filter. Even though the systems metaphor has predominated, influential work has

Table 40.1 Criminal Justice Theoretical Orientations

<i>Major Features</i>	<i>Packer's Crime Control vs. Due Process</i>					<i>Late-Modern</i>
	<i>Rational/Legal</i>	<i>System</i>	<i>Politics</i>	<i>Social Construction</i>	<i>Growth Complex</i>	
Intellectual tradition	Neoclassical Legal formalism	Structural-functionalism Biological sciences Organizational studies	Political science Public administration	Interpretive school Symbolic interaction Social construction	Weber Frankfurt school Critical public administration	Foucault Governmentality literature Postmodernism
Key concepts employed	Rational-legalistic, rule-bound Taken for granted	Functional Equilibrium Efficiency Technology External forces Open system Closed system	Ideology Conflict Symbolic politics Policymaking/implementing State, community	Myth Reality Culture Symbols Legitimacy Moral panic Impression management Institutional theory	Bureaucracy building Privatization profit Complex Technical rationality Merging complexes	Actuarial justice Neoliberal politics Exclusive society Safety norm Incoherence in CJ policy
Why the rapid CJ expansion in the last 30 years?	Legal reaction to increased lawbreaking (forced reaction theory)	CJ system reacting to increases in crime (forced reaction theory)	Politicians exploiting problem Politicized drug war Shift in ideology	Moral panics Media exploitation Runaway cultural process Crime as scapegoat	Dynasty building Growth complex Merging private with public CJ with military	Crisis in state sovereignty Risk-averse society Growth complex Moral indifference

<i>Major Features</i>	<i>Rational/Legal</i>	<i>System</i>	<i>Packer's Crime Control vs. Due Process</i>	<i>Politics</i>	<i>Social Construction</i>	<i>Growth Complex</i>	<i>Oppression</i>	<i>Late-Modern</i>
Assumptions about agency and practitioner motives	Well-intended Protecting Serving Rule following Law abiding Professionalism	Rational decision makers Efficient Adapting to external forces	Role/goal conflict Mixed messages Mimic the value messages provided from public	Responsive to politics Interest based Ideological pulls Power players	Constructing problems for existing solutions Reacting to moral panics Culturally bound Managing appearances	Self-serving Power-building Quest for immortality Means over ends Bureaucratic survival Technical over moral thinking	Institutional racism, sexism, classism Often unaware of oppressive end result of their own activities	Navigating through massive transformations, late-modern forces Good intentions, disturbing results
Issues of concern	Deterrence Defending the virtues and honor of the CJS	Abuse of discretion cutting-edge technology Streamline/centralize operations	Erosion of constitutional rights Governmental intrusiveness	Federalization Symbolic politics Ideological intensification	Media/ bureaucrat/ political exploitation Mythology Symbolic policies War rhetoric Images of race/gender	Exponential growth Private/public Military/police blur	Violence against women Drug wars impact on marginalized Racial profiling	Growth of system Changes in social control Rise of surveillance society

NOTE: CJ = criminal justice; CJS = criminal justice system.

also used the interpretive orientation (social constructionism/cultural studies); the political framework; the oppression orientation; and, most recently, has studied criminal justice through the lens of late modernity.

The late-modern lens situates the criminal justice apparatus (broadly defined) within macroshifts associated with the current era of human history labeled *late modernity*. Criminal justice and crime control phenomena are best explained as adaptations to five late-modern social conditions:

1. The rise of actuarial justice and the influence of the risk society
2. A neoliberal shift in macropolitics
3. Increasing contradictions and incoherence in crime control policy
4. The decline of sovereign state's legitimacy
5. The ascendance of an exclusion paradigm for managing individuals perceived as posing a safety threat in an increasingly security-conscious society

The late-modern orientation is probably the most theoretically vigorous pursuit of criminal justice/crime control phenomena in the literature today.

Conclusion: Theoretical and Disciplinary Integrity

In 1998, Marenin and Worrall asserted that “criminal justice is an academic discipline in practice but not yet in theory” (p. 465). Scholars in the field have not placed high value on this endeavor for two primary reasons. The first has already been discussed: Crime theory suffices. The second is more difficult to overcome: Although exploring the why of crime has *prima facie* importance, our field has neither articulated nor acknowledged what value theorizing criminal justice provides. Some people assume, in fact, that studying criminal justice is inherently and necessarily atheoretical because it concentrates on practice. The notion that practice can somehow be severed from theory has been thoroughly debunked in most other major fields of study (Carr & Stephens, 1986; Fay, 1977; Habermas, 1972). Theory and practice are implied in one another; no policy analysis, implementation, strategic plan, or practitioner action is devoid of theory. To deny the integral role theory plays in all these instances is to remain ignorant of its influence.

In a sense, then, theorizing criminal justice is an inherently critical endeavor providing important insights into the systems irrationalities, missteps, and disconcerting implications. Numerous criminal justice issues guide our analysis: the criminal justice apparatus's steep growth in size, power, and punitiveness; controversial new initiatives in the wars on terrorism and drugs; and disparities in the treatment of minorities, women, and the poor. Each of these objects of study necessitates a scholarly scrutiny of immediate causes as well as their larger theoretical context (cultural, political, economic, and sociological forces). Of course, the level at

which this scrutiny is carried out will vary, ranging from a critique of a single administrative practice to perhaps a wholesale critique of the criminal justice growth complex (see Table 40.1, “Growth Complex” column). Theoretically based scrutiny focused on criminal justice and crime control should not be misconstrued as inappropriately critical. It is simply approaching criminal justice as a research problem—similar to the way crime is studied.

Theorizing criminal justice phenomena should also not be viewed as an endeavor intended exclusively for practical change. Numerous scholars in the field find the study of society's reaction to crime intellectually stimulating in and of itself—much like a biologist studies the animal kingdom or an astronomer studies the solar system (see Kraska & Neuman, 2008). The study of humans and organizations attempting to control wrongdoing (and sometimes engaging in wrongdoing while trying to control it) yields intriguing insights about the nature of society, the political landscape, and cutting-edge cultural trends. In short, how we react to crime tells us a lot about ourselves and where our society might be headed.

Theories are repositories for substantive thought; impossible-to-avoid filters for thinking through history and major contemporary issues and trends; the foundational material through which innovative solutions to problems are developed; and the backdrop for all research in the field, whether policy based, descriptive, or theoretical. Numerous contemporary scholars are beginning to study criminal justice using more modern conceptions of systems theory, social constructionism, Foucauldian theory, feminist theory, and late modernism. The time appears right for scholars in the field to begin placing a higher value on developing a theoretical infrastructure about criminal justice. Criminal justice theory should become a normalized presence in the criminal justice and criminology degree programs, its textbooks, and its doctoral training. Nothing less than our disciplinary integrity is at stake.
